In an introduction to curriculum development for data science at the school, Biehler and Schulte (2018) define two roles for future students with regard to data science: either working as data scientists, and then probably having additional education on an academic level, or in the role as users, exploring existing systems, developing simple system models. They should then be able to make the black boxes more transparent and identifying underlying assumptions, including economic, political, and cultural conditions and interests. Therefore, it is necessary to take into account economic, societal, and cultural conditions and implications (Harari 2017; Weigend 2017; O’Neil 2017; Aoun 2017): “For a data science curriculum, the question is how to educate students so that they can take a thoughtful position in these debates, and on a more practical level, how to integrate societal issues with formal and technical aspects of data

science as a scientific discipline. The societal aspects include questions about providing private data to companies, critical media competence, “News competence” (dealing with “fake news”), statistical literacy (media reports including products from data journalism and scientific studies using data), and using data and/or data science for one’s own goals and in everyday situations.” (Biehler and Schulte 2018). In summary, a DS curriculum for schools needs to take into account the following aspects: the fundamental ideas of data science as a discipline and the societal debate and impact of data science on society as a whole (Mau 2019) and individual life – and therefore the curriculum has also answer how it contributes to general education and the formation of the individual self. Biehler and Schulte (2018) thus proposes to conceptualize data science education and data projects in the context of so-called “hybrid” systems (Biehler and Schulte 2018; Schulte and Budde 2018; Rahwan et al. 2019). In a report on the future of jobs, the consulting company Cognizant formulated the idea of a hybrid system in terms of a future job, named “Man-Machine Teaming Manager,” whose task is to “help combine the strengths of robots/AI software (accuracy, endurance, computation, speed, etc.) with the strengths of humans (cognition, judgment, empathy, versatility, etc.) in a joint environment for common business goals. [...] The end goal is to create augmented hybrid teams that generate better business outcomes through human-machine collaboration.” (Pring et al. 2017, p. 30). By replacing the focus on business with a focus on society and societal aspects in general, the impact of this view becomes more apparent for education. In Schulte and Budde (2018), a first attempt has been made to further elicit this perspective. We hope that the notion of hybrid systems helps to integrate societal aspects and to open up black boxes.

DSE Tools and Infrastructures

In order to learn or teach data science, computational tools are needed Çetinkaya-Rundel M, Rundel C (2018).

At the level of higher education, DSE tools and development environments can be used that will later be applied in the professional environment of

DS and which must, therefore, be mastered by the learners (see above). Some of these professional tools like R-Studio, Gapminder, Tableau are highly scalable and therefore also suitable for the educational use in secondary education.

For the use on the secondary level, one can broadly distinguish two types of DSE-tools:

On the one hand are interactive tools like spreadsheets, which let one directly manipulate and visualize data. For example:

- CODAP is open source educational software for data analysis. The web-based DS tool is designed as a platform for developers and as an application for students in grades 6–14 (<https://codap.concord.org>).
- *Fathom* is an easily to handle DS tool for students that quickly represent data in a variety of different and supports students in understanding math concepts like algebra, precalculus, and statistics (<https://fathom.concord.org>).
- *iNZight* is also a DSE tool especially developed for students in lower secondary schools. It has a drag-and-drop interface, which automatically detects the variable type (numeric or categorical) of the input data and thus enable students to easily create graphs of the input data (<https://www.stat.auckland.ac.nz/~wild/iNZight/index.php>).
- *TinkerPlots* belongs to the same class of DSE tool for students in grades 4 and up. It has, e.g., a sampler engine, that allows students to design and run probability simulations and visualize the results over many samples (<https://www.tinkerplots.com>).
- *Orange* is also a machine and data visualization tool for novices and experts, that allows to explore statistical distributions and even multi-dimensional data structures (<https://orange.biolab.si/>).
- *Tableau* is a more professional computing environment for the visualization and the graphical representation of data and resulting information to support data-driven decision-making (<https://www.tableau.com/learn/articles/data-visualization>).
- *Gapminder* is a data visualization tool that is dedicated to explore the massive amount of

global statistics und uses photos to give numbers a meaning and thus creating a “fact-based world view” (<https://www.gapminder.org/for-teachers/>).

On the other hand are tools like RStudio (see description above) or Jupyter Notebook, in which data manipulation is done by using programming languages like R or Python.

Jupyter Notebook: With the software tool Jupyter Notebook, one can build digital documents, which are then also called Jupyter Notebook. The tool can be seen as a programmable digital notebook, which contains texts, links, pictures, videos, and also sourcecode snippets can be integrated and executed within the document. Notebooks can be shared with other people in many different ways, exported in various formats and, for example, packed into a Github repository. Jupyter Notebook scales well and therefore runs on a desktop, in a large cloud or on a configurable multiuser server (Jupyter Hub). Therefore, this universal tool is also very well suited for the analysis and visualization of big data in DSE (<https://jupyter.org/documentation>).

The first type of tools relies on the “What you see is what you get” and “direct manipulation” paradigms, which aim to create the impression that the user directly works with the data and gets direct feedback. Programming on the other hand is more indirect, as first a set of data manipulations is coded in a formal syntax and then applied. Both approaches have their merits and fallbacks; e.g., WYSIWYG-tools are easier to use, but programming tools are better for checking how data was manipulated: one can change the script and run again on the original data. Both types of tools can be introduced and reflected on by the students.

From the computing education perspective, the intention is not only to use tools in order to learn data science (learning with tools) but also to learn about tools and their role in data analysis. Learning about tools includes understanding the role and influence different tools have on the data science process and to understand that tools are designed and constructed for a purpose – and hence that tools can be redesigned. Often, easy-to-use interactive

tools are not readily open for redesign by a user, whereas the more programming-like tools afford and inspire adaptation to one's own need.

Finally, a type of tools should be mentioned, which makes the calculation processes and the dataflow between them visible and at the same time uses neural networks for the analysis of the data. The DS-tool TensorFlow (see description above) belongs to this class of tools.

Supplemented with Keras (see Chollet 2017; The Keras Blog 2019), a simple and modular deep learning library for Python, this computing environment is also a powerful tool for data analysis in DSE.

DSE and Relation to Other Subjects

DSE: Relation to Computer Science Education

In curricula for computer science education (CSE), already aspects of data science are included. In the CSTA curriculum, e.g., the following data science-related content areas are included:

- Use data analysis tools and techniques to identify patterns in data representing complex systems. For example, identify trends in a dataset representing social media interactions, movie reviews, or shopping patterns.
- Select data collection tools and techniques to generate data sets that support a claim or communicate information.

“Evaluate the ability of models and simulations to test and support the refinement of hypotheses” (CSTA 2017), p. 27. Students shall acquire these skills according to the CSTA K–12 recommendations within the data-related topic areas “Collection, Visualization, and Transformation,” “Hypotheses,” and “Inference and Models and Algorithms.” In a conceptual description of a modern CSE curriculum in the UK, the Royal Society also emphasizes the significance of big data: “The opportunities provided by new computing curricula coupled with advances in technologies and analytical tools with which to mine big datasets, and the increasingly interdisciplinary nature of educational research, offer enormous scope for advancing computing

teaching and learning” (Royal Society (Great Britain) 2017), p. 96.

On the other hand, CSE curricula comprise essential areas of competence that are not in the focus of DSE, for example, exploring and understanding informatics systems concerning their externally visible function and their internal structure. The results of that kind of exploration will enable students to enhance their informatics systems and to design and to develop new ones. In doing so, the respective socio-technical application context of the informatics systems and the capabilities and the potential interests of the users are to be considered. These kinds of questions and fields of competence are the focus of various CSE approaches that regard informatics systems as socio-technical systems. However, as noted above, another goal of data science education is to open up the black boxes of data-driven products and systems people encounter in their everyday use of digital devices.

So far, computer science curricula tend to focus on constructing artifacts and not so much on the analysis, evaluation, and societal reflection of existing artifacts (Schulte et al. 2017; Tedre et al. 2018). This general orientation is at least in part due to the nature of the discipline of computer science itself, that also merely focuses on designing and developing artifacts (Tedre 2014), so that the idea of focusing on analyzing existing artifacts or machines, seems like a change of perspective, and as one that forces more substantially to include interdisciplinary approaches (Rahwan et al. 2019).

Another interesting relation of data science, and more specifically machine learning, is the change in the process of designing and problem solving itself. From the beginning of computing education, a core goal and rationale was the tight connection to problem-solving. Problem-solving, according to Polya (2014) is a process and an approach to find a way to overcome a barrier between the task at hand and the solution, because the immediate way how to solve the problem is often not clear. One approach is heuristic problem-solving, where a solution is designed, tested, and then refined. Heuristic problem-solving is supported by stepwise refinement and a top-down process. In structured programming,

the problem solver/programmer stepwise refines the solution from analysis, design to implementation. In a more abstract point of view, two phases are most important for this process and for education: The problem solver/learner first analyzes the problem, and second, designs a solution. The important aspect is, that the problem (analysis phase) and the solution (design phase) are needed to be deeply understood. Therefore, computer science core educational goal is learning this kind of problem-solving. In early days, it was referred to as programming, then as algorithmic thinking and also (as it is now) as computational thinking. This important core of CS education is now challenged, and at first sight maybe even obsolete by machine learning, because the problem-solving process dramatically shifts towards machine learning, in which the computer now fulfills the process of heuristic problem-solving by a process of trial and error. During this process, a model of the problem, which is also a model of the solution is developed by the computer, and the human problem solver/learner probably does not acquire a deep understanding of either the problem (analysis) or of the solution (design).

The machine learning problem-solving process changes the role of the human: Instead of analyzing the problem and designing a solution, the human collects example (in other words: data) of the problem together with possible solutions (in case of supervised learning): for example, picture analysis, e.g., number recognition, face recognition, object recognition in general, huge amounts of data are collected that show examples together with their solution. For example, pictures of handwritten digits, together with annotations what digit is seen. Or pictures of twins or chips, with a label. The role of the human is then to collect and label such data and feed it into the machine learning mechanism. This mechanism then develops a model for recognition that can be used to also recognize the elements in new examples. However, the human problem solver does not necessarily acquire deep knowledge about the problem. Instead, the model built by machine learning is a black box. This phenomenon leads to a shift also in CS research: e.g., accountability, explanations, or even a debate on new research areas (Rahwan et al. 2019).

DSE Relation to Math Education

In higher education, the scientific examination of DS methods and concepts requires, among other things, specific mathematical knowledge at the university level. As a result, most undergraduate curricula contain mathematical methods or are expected to be acquired by students in mathematics courses (Tang and Sae-Lim 2016). The main question here is not whether DS methods should be integrated into mathematical higher education, but which mathematical topics should be acquired within the framework of a DS course.

The situation is different in the area of secondary education, where DS is usually not an independent school subject. Here, among other things, there is also the question of whether parts of DSE can be integrated into mathematics teaching.

Many of the mathematics curricula have a similar structure to the NCTM curricula and are structured in terms of process and content dimensions. (NCTM 2019).

The process dimensions mostly include “problem-solving, reasoning and proof, communication, connections, representations.” Areas such as “Number and Operations, Algebra, Geometry, Measurement, Data Analysis, and Probability” are assigned to the content dimensions in many mathematics curricula.

In order to present a more precise correlation between DSE concepts and mathematical competence requirements, one would have to look at the curricula for the individual grades in detail. In the context of this entry, it is only possible to reveal potential links between elements of mathematics learning and teaching and DSE concepts on a general level. These arise both about the content and the process dimension of the mathematics standards.

For example, especially the contents from “Measurement,” “Data Analysis and Probability,” and “Number and Operations” are relevant for the adequate handling of data and DSE tools. In the data-oriented modeling of DS questions and the presentation of the results, almost all mathematical process dimensions are affected in different ways, depending on the specific problem.

It should be noted that, on the one hand, mathematical knowledge must be assumed in order to

use DSE methods and tools successfully. On the other hand, the use of DSE tools in mathematics teaching also opens up the possibility of acquiring and deepening mathematical knowledge.

In order to enable that kind of learning, some of the tools developed for school lessons (e.g., TinkerPlots, iNZight, see above) are already designed for use from fourth grade on, considering the mathematical knowledge available to the students. The tools are also suitable for further facilitating the students' mathematical understanding.

In connection with the use of DSE tools in math classes, the relation to computational thinking (CT) and the "big Ideas" of important computing principles also arise. Since, e.g., the handling of data and the presentation of the computing results illustrate the importance of computers and software tools also during math lessons, the students can thereby also acquire further competencies in the sense of CT (Wing 2006; Standards for Mathematical Practice 2019).

Some of them are: "Abstraction reduces information and detail to focus on concepts relevant to understanding and solving problems. Data and information facilitate the creation of knowledge"; "Algorithms are tools for developing and expressing solutions to computational problems"; "Programming is a creative process that produces computational artifacts"; "Digital devices, systems, and the networks that interconnect them enable and foster computational approaches to solving problems"; and "Computing enables innovation in other fields, including science, social science, humanities, arts, medicine, engineering, and business."

However, it should also be noted that the DS methods also concern contents and concepts in mathematics teaching that have not yet been genuinely the subject of mathematics teaching (Biehler and Schulte 2018). Although, for example, elements of stochastics, probability theory, and statistics can be the subject of mathematics lessons, further mathematical problems must be dealt with in connection with DSE topics:

"Problems of measurement (operationalization of variables, adequacy problem); Biases in sampling; Distinguishing observational studies from experimental studies; Random assignment and the

problem of confounding variables; Simpson's paradox; ecological fallacy; Confounding of conditional probabilities; Understanding visualizations of complex data (including interactive ones)" (Biehler and Schulte 2018).

Therefore, the successful implementation of DSE projects might require some modifications in traditional math curricula, especially in upper secondary education, considering the issues addressed above.

DSE Relation to STEM and Social Sciences

At the level of higher education, DS methods are used in many subjects, above all for empirical research but also in teaching, where DS methods can illustrate subject-related, empirically founded evidence. In this respect, at least the acquisition of basic knowledge of the methods of Data Science is envisaged in the curricula of many subjects, especially in economics, natural sciences, but also social sciences (De Veaux et al. 2017; Tang and Sae-Lim 2016).

At the level of secondary education in schools, DS methods are used to evaluate empirical data, particularly in the natural sciences and social sciences. In these school subjects, DS methods enable students to discover subject-related interrelationships. In STEM, DS methods can be applied, for example, to evaluate large amounts of sensor data and other publicly accessible more extensive collections of measurement data. In social science subjects, the publicly accessible data collections and statistics on social, geographical, economic, or political problems can be used similarly (see above, projects with Gapminder).

The students can achieve the necessary DS-related basic knowledge, mainly in computer science education and mathematics. The subject-related applications of DS-methods in the other subjects can contribute to deepening the students' DS knowledge they have acquired during math and informatics lessons. Therefore, on the one hand, it is necessary to coordinate the school curricula of the subjects concerned accordingly.

Since, on the other hand, DS-related content in the subjects of computer science and mathematics cannot be imparted without an application context

and particular content reference to areas of other school subjects, interdisciplinary cooperation and, if possible, the organization of interdisciplinary project teaching is always appropriate in DSE. Examples of such projects have already been described in the discussion of DSE project phases (see above).

Conclusion

The entry showed that data science and data science methods have become very important in many areas of society. In this respect, DS-related courses of study have been established in higher education and the further training of IT professionals. Furthermore, the anchoring of DS contents in the curricula can be observed even in courses of study that are not directly related to computer science or mathematics.

In the field of secondary education, there are several relations between Data Science Education, Computer Science Education, and Mathematics, especially in the field of Data Science methodology. Since the subject areas of the vast data collections and possible related evaluation tasks mostly also concern other school subjects, interdisciplinary cooperation is necessary.

For learning and teaching purposes in nearly all school subjects, various open source tools are available. These tools are suitable for students, partly already from grade 4. Through these tools and numerous extensive data collections, subject-related and comprehensive interdisciplinary Data Science projects can be realized in many subject areas of secondary education.

Definition

Decision support grew out of theories of organizational operation and improvement that encouraged the development of technical systems to help organizations act more rapidly and with more confidence. They did this by applying algorithms based on historical data and on curated resources – both data representation and documented organizational responses to similar data patterns in the past (knowledge codified for reuse). There is, therefore, symbiotic and reinforcing relationship between decision support and knowledge management. The operational success of current decisions is then fed back into the system to evaluate the efficacy of the underlying models.

Introduction

In a period in which large amounts of data from online educational solutions are readily available and analytical approaches are maturing, it is important to think about how to best leverage the results of emerging analysis. This is why one considers knowledge management in combination with decision support. Making evidence-based decisions is the core factor in continuous improvement, but decisions can only be made around the evidence base (the stock of knowledge) about what *can* work. More formal methods of organizational improvement (improvement science) rely on a mature infrastructure of managing and evaluating evidence (decision support) and accumulating and sharing information about what works (knowledge management). There are a growing number of examples of both school and higher education organizations building substantial technical capabilities to link evidence to action. What is particularly compelling is examples of large organizations making substantial changes to the way that work (student services, advising, instruction) is carried out and evaluated. We now have existence proofs that even the largest educational institutions can make substantial improvements and link those improvements back to their decision support systems. At the same time, decision support is moving beyond simple analysis of historical trend. We will see that in both administrative support systems and student-focused learning systems, predictive analytics are being leveraged to inform real-time responses to student behavior – with an underlying predictive warrant.

Recent History of Decision Support and Knowledge Management

There is a long history of the study of organizational decision-making, algorithms to support management decision-making, and the representation of analysis using graphics (Shim et al. 2002). It has been only in the last 15 years that large segments of the educational enterprise

have moved beyond old transactional systems to more integrated, enterprise-wide tools. This was a slow buildup of capacity. Narrowly focused student information systems were linked to human resources and counseling systems through new data standards (SIFA, PESC, etc.). Likewise, the large learning management systems ceased to be isolated data islands as new standards (e.g., LTI) for integrating more specialized personalized learning packages became mature. Behind all of this, increasingly modular infrastructure was also a growing level of maturity in data warehouse solutions and analytical tools that could help bring structure and apply statistical analysis.

What was missing was any depth of knowledge about what to do with this mountain of data. A number of firms (e.g., Knewton, Summit Learning, Class Dojo, etc.) have made claims of effectiveness, but there is little still limited evidence about how best to leverage these vast wells of data. Indeed, the evidence available suggests that the road to successful application of new decision support models must be supported by change solid management skills in organizational leadership. Georgia State is one of the most well-researched (if not well-understood) examples of a large university that has used effective decision support techniques and a collaborative approach to knowledge management to eliminate the correlation of race and ethnicity with graduation rates (BMGF 2015). A number of other institutions have adopted the software tools used by Georgia State, but no one has replicated the results. It's clear that the solution is not simply technical.

We can see similar dynamics driving much of the evolution of resource development in the US market (Alamuddin et al. 2016). In the K–12 sector, much of the past decade has been focused on developing clear standards for learning (Common Core) and more technical measures of school and educator effectiveness (test-based, growth models). This included a decade of work to improve the ability of student information systems to get the attribution of what adult(s) taught which subject to each student over any given

period. Before the latter part of the first decade of the new millennium, most school systems would not have been able to provide that attribution.

At the same time, one saw the rise of performance-based funding in public higher education – rewarding post-secondary institutions for student persistence, completion, and earnings post-completion. The demand on data systems and data quality that these policy shifts have required has been enormous. At the end of the first decade in the 2000s, very few states or districts could have accurately reported which students were taught what subjects by a particular teacher. K–12 student information systems were designed to ensure contract student-teacher ratios were maintained and class sizes were appropriate for the physical space allocated – not track teaching. Likewise, for higher education institutions, getting math and English placement correct and supporting struggling students to persist and complete did not matter financially, since all students' credit hours generated the same revenue for the institution. Those data simply weren't even tracked (remedial placement is still not tracked at the federal level).

The ability to track instruction (and other services) also made the creation of district and then statewide information systems possible. In the USA, many states received Statewide Longitudinal Data System grants to create the infrastructure to track student data from pre-kindergarten through graduate education. A number of states have extended that coverage to include early childcare, health, and employment data. What's still missing in most of these systems is any details about the adult practice associated with student outcomes. It is now possible to track that amount of math instruction, for example, a given student has received over the course of a year or even the series of courses a student took over a set of years – potentially including both secondary and post-secondary education. However, there is very little data available about the content of the course or the instructional practices used to support student learning.

At the student level, the widespread use of technology tools for education (learning games, learning management systems, personalized

tutoring systems, etc.) has also led to an explosion of micro-level data about student activity and outcomes at the individual quiz or game decision point level. While these data can be mined to create maps of students' abilities (as measured by these online assessments) and estimates of student engagement (using time stamps between actions), there is often little data that connect the individual student online work to practices or larger instructional intent in the classroom.

The history of knowledge management is much less developed during this period. If one considers the ongoing tension around competing definitions of knowledge management, it is not surprising that one does not see widespread acknowledgement of tools or practices in the education literature (or software offerings). One can see a thorough line between early efforts at knowledge management in education that have become more mature based on improvements in technology and supportive policies/investments. For example, a common knowledge management application for educators over the past 20 years has been the creation of resource repositories with associated metadata frameworks to support the location of resources that could be combined to create more sophisticated educational artifacts. In the USA, efforts such as the National Science Digital Library from the National Science Foundation or a number of curricular repositories created by private philanthropy were built around a “build it and they will come” strategy. MERLOT was an international effort from that period designed to make it possible to store, rate, and share educational resources. The Hewlett Foundation led efforts to build capacity across the sector to produce high-quality open-source resources. They did this through direct investments and by supporting the work of the Creative Commons. Staff from the Creative Commons began meeting with education officials across the USA in the early 2000s to support collective action between US education leaders. Serving as a digital repository is the most common form of knowledge management project in education. It is built around the notion that educators at all levels have little time to create unique curricular content

but do want to search for an assemble components across multiple collections to build hybrid materials for their courses. It is not clear how well such models align with the skills of most educators or the time they have available. There have been more concerted efforts in recent years to use open resources in post-secondary education to reduce the costs of materials for economically disadvantage students. Several states have partnered together to make resources searchable across multiple repositories. Again, these efforts suggest that location of resources is the primary goal. There are no aligned process or professional learning resources to support the adoption of new practices that are associated with more modern curricula.

The other common uses of knowledge management systems are only beginning to emerge in the education sector. Expertise location is a function that emerged early in professional service firms and in manufacturing. Given the isolation of classroom practice at all levels and lack of consensus on practice, it is not surprising that expertise location has not been widely used by formal institutions in education. However, both small and large technology companies are using individual teachers as brand spokespersons through social media (Singer 2017). Individual teachers are then compensated by these firms for opening their classrooms to share their personal practice in the use of technology tools.

Challenges and Benefits of Decision Support and Knowledge Management

The proliferation of tools available to support both classroom instruction and individualized practice and learning outside the classroom offers insights into instructional practice and learning on smaller and smaller time scales. The nearly ubiquitous use of learning management systems provides educators and administrators with outcome data on both low- and high-stake student assessment. Recent innovations from companies such as BrightBytes and Clever (Herold 2018) provide administrators and teachers with near real-time data on the use of

a range of learning tools so that not only outcomes are available to support decision-making but patterns of use as well. The broad availability of microdata on student outcomes holds the promise of supporting individualized student learning. However, the rewards of such systems remain elusive (Herold 2017) at scale, according to a series of studies conducted by the RAND Corp. The translation of what works in limited contexts to a set of broadly deployable set of solutions is the knowledge management challenge facing the sector. RAND study points to the challenges associated with designing and supporting a diverse set of student-facing resources. This highly sophisticated and demanding work requires that schools and districts allocate substantial resources to supporting time it takes to design, test, and share effective materials.

One of the primary limits to this work are the gaps in knowledge around what works for improving student outcomes across varied contexts. It is possible that broad-scale classroom experimentation could yield usable knowledge, given the widespread use of the tools described above, but the lack of alignment in standards for student learning and the wildly varying models for resource allocation, undercut the ability to answer the *what works* question.

The limits of the potential of the application of decision support and knowledge management are not technical. The ability to federate data across multiple systems and apply mature analytical frameworks are widely available. Knowledge management tools such as Google for Education, Box, DropBox, BaseCamp, etc. provide ample support for collaborative content creation and curation. Sophisticated support for metadata and search allows for easy discovery and sharing. The limits of the available tools are based on the norms and politics of the sector. Schools are still mostly organized as relatively autonomous instructors with little time for collaboration and led by administrators with too many direct reports to develop well. The incentives in most educational systems are still focused on student accountability as the primary driver instead of the communities obligation to deliver effective schools to students.

The Promise of Decision Support and Knowledge Management

Using big data from individualized learning applications to create predictive models for personalized support to tackle problems at the student level has enormous potential power (Agasisti and Bowers 2017). Using big data from historical records to build wrap around services to intervene outside the classroom (from community schools to Georgia Tech) and creating research-practice partnerships (or at least formal networks) to tackle persistent problems of practice could take advantage of the transparency provided by tools that allow use of federate outcome data across a heterogeneous set of learning technologies. Schools and support organizations (New Visions for New Schools, High Tech High, Rocketship, Summit, etc.) that have moved away from traditional organizational models and made continuous improvement a core part of their missions show that change is possible and that students furthest from success can achieve great outcomes.

Summary

While there is enormous potential in the education sector for the tight linkage of what is known with one's ability to use that knowledge in real time, the evidence base around efficacy is still quite thin. The promise of individualized learning seems to be something one must still anticipate.

Design: Teaching programming is more than just teaching the syntax of a programming language, novices should be taught how to create programs, including how to design them (Soloway 1986). Design in K-5 programming projects is a creative process which takes an idea, task, or problem (a goal) and produces a design which can be implemented as code. The term design is both a verb (describing the process of creating a design) and a noun (the actual design artifact created).

The design artifact, for most young K-5 programmers, could be a remembered or recorded discussion about what they are going to make; an informal diagram, such as a storyboard, concept map, or labelled diagram; or a written note detailing their ideas. Some older learners might use flowcharts or pseudo code to more formally document their design. Within design artifacts algorithms are represented in a variety of simple

ways. The algorithm can be represented by an ordered set of photographs of a physical enactment of the planned program, the numbering of storyboard pictures to show the required sequence of events, or a written rule such as how a score in a quiz should work. (In simple terms, an algorithm is a set of steps or rules that make something happen or work something out.)

The process of creating a design used by learners will vary. Some learners will be aware of the path ahead; others will not. Some learners may design “on the hoof” with no thought of what will come next until they finish coding what they are currently attending to. Others may plan a few elements “ahead” before starting to code. Some might sketch out the whole of their solution in some detail before they start any coding. How young learners approach debugging, finding, and fixing errors in their code, will also vary, some will debug as they go along understanding they will code and debug each part in turn, evaluating and revising their design as they go along. Others might wait right until the end of their development.

Some learners will work “top-down” by creating and using a plan; others will explore and build “bottom-up.” Most are likely to use a mixed approach, sometimes thinking ahead, sometimes exploring and reacting to opportunities presented. Whichever approach is taken the underlying objective is for pupils to think, design, and learn by making a digital product (Kafai and Resnick 1996).

Programming Projects

Young pupils in K-5 education across the world are being introduced to the world of computing through learning to code. Early experiences include using programmable toys or simple programming languages with an initial focus on learning how to program simple sequences. As learners progress further, programming constructs such as loops, selection (if, then statements) are introduced as well as simple data structures such as variables and a variety of inputs and outputs including microphones and motors (K-12 Computer Science

Framework Steering Committee and Others 2016; Department Of Education 2013). Often educators create learning experiences to teach programming using projects to situate learning. Project goals could be suggested by teachers or pupils. It is likely that goals will include an audience, purpose, and genre of a task, as well as constraints such as the coding language (software) and hardware to be used. Genres of programming projects include route-based activities, puzzle-based scenarios, animations, quizzes, games, control (physical computing), and simulations and modelling.

Projects might include

“Make a James and the Giant Peach story mat for our programmable toys and make some route challenges for your class (don’t forget the answers too).”

“Using Scratch, create a simple animation of your favourite things for your next class teacher.”

“Using Logo, create a shape picture for a Celebration Card for your family.”

“Using Blockly, create a simple maths quiz for 6-year-olds to help them learn their doubles.”

“Using Kodu, create a game to help teach road safety for a national competition.”

“Using a Makey, Makey, Lego Wedo or Crumble Controller (or other physical device) make an interactive display about our current topic, Rainforests, for our family open day.”

How programming is taught varies. An approach favored by some is tightly scaffolded learning experiences giving pupils code to copy. Other strategies include solving predefined coding puzzles, using, modifying, and then creating new projects, remixing code, learning to read code before learning to write code, apprenticeship, guided exploration and tinkering (learning by exploration and trial and error). Several recent studies have suggested a combined approach of a range of strategies might be the most effective approach to teaching programming (Grover et al. 2015; Hansen et al. 2016). A blended approach might include targeted tasks that teach specific skills, including reading code and debugging tasks; live coding where the teacher demonstrates

design, coding, and evaluation; guided exploration where pupils explore a limited set of code blocks for a specific outcome; project work, including graduated support starting with pupils imitating good quality exemplar projects, then moving on to remixing, evolving, and changing example code to finally independently creating brand new inventions; as well as some copy code and tinkering if needed.

Whatever approach is used to teach programming, the role of design is not always clear, and there is limited research in this area. Notable exceptions to this include: investigations of the simplified Engineering Design Process with Kindergarten pupils learning about robotics (Bers 2017), a middle-school study of crafting and programming including creation of design artifacts (Kafai and Vasudevan 2015), and the introduction of the agile methodology (incorporating a design process) with high school students (Kastl and Romeike 2015; Missiroli et al. 2016). Despite some emerging research in design and programming for young learners, research related to design and computational thinking within classroom settings is even more sparse.

Design and Computational Thinking

Computational thinking has been suggested as the basic skill needed to learn to program. Proponents describe a variety of computational thinking concepts, approaches, practices, and techniques (The College Board 2017; Csizmadia et al. 2015). Concepts might include abstraction, decomposition, generalization (spotting patterns and using similarities), and algorithms. Approaches, practices, and techniques such as tinkering, creating, debugging, collaborating, persevering, reflecting, analysis, designing, and coding are suggested. Despite a lack of consensus of exactly what computational thinking is, and of its usefulness (Tedre and Denning 2016), abstraction is cited as being a cornerstone of computational thinking (Wing 2008). Abstraction has been defined as reducing unnecessary detail and generalizing solutions. In creating

designs, abstraction is needed, as the designer must decide what must be included and what can be ignored. Similarly, as the designer breaks the problem down into parts, they are decomposing their solution. In detailing parts of the design algorithms are included. This might be in the form of the ordering of action, or in defining the rules to be implemented. If storyboarding an animation, the order of events is the algorithm. If designing a quiz or game, a written rule for maintaining a score is an algorithm. When designing a project to have reusable components pupils show they can generalize. For example, if designing a program to create a shape picture, learners might include the idea of a generic shape drawer, which uses the number of sides of a shape to draw any shape, rather than having separate, distinct components to draw each different part.

The relationship between design and computational thinking has not yet been fully explored, and research is very limited in this area. However, there is much research related to planning in other subjects that could inform pedagogy associated with teaching design in programming.

Planning in Other Subjects

In other school subjects, some teachers request that pupils plan their ideas for a substantial piece of work. For example, in story writing storyboards might be used to provide an overview of the key events to be included. In creating a history report a concept map might be used to highlight key themes. In design and technology lessons labelled diagrams provide an overview of the product to be made. In dance a choreography can be developed through a series of stick figure drawings. The plan separates the process of gathering and evaluating ideas from the process of implementing these ideas in the finished project. Once created the plan provides an aide-mémoire of what is to be done, allowing pupils to self-manage the implementation phase and supporting independence. Research in learning to read and write indicates that setting goals, planning and understanding a process for

accomplishing tasks leads to improvements in self-efficacy, self-regulation, and progression in learning (Dockrell et al. 2015; Graham and Perin 2007; Schunk and Swartz 1993; Tracy et al. 2009; Whitebread and Basilio 2012).

Processes and design artifacts used in Design and Technology lessons such as following an Engineering Design Process and using exploded labelled diagrams can be particularly useful for programming projects which incorporate physical computing. Teaching coding with robotics and tangible programming languages in kindergarten, the research team at Tufts University have developed curriculum materials and a simplified Engineering Design Process of ask, imagine, plan, create, test, and improve and share (Bers et al. 2014) as shown in Fig. 1.

There may be opportunities to use familiar cross-curricular planning tools from a range of subjects in programming projects as design tools. However, research on what design might look like in K-5 programming projects is limited as is pedagogy on how it should be taught (Waite 2017).

Design in K-5 Programming Projects, Role of, Fig. 1 A simplified engineering design process from Tufts University's programming and robotics curriculum unit (2010). (<http://ase.tufts.edu/devtech/tangible/Classroom%20Curriculum%20Version%201.02%20Nov%208%202010.pdf>. © DevTech Research Group, Tufts University)

Levels of Abstraction

A levels of abstraction framework has been suggested to support investigation of university students’ understanding of algorithms and learning to program (Armoni 2013; Perrenet et al. 2005). Studies using this framework indicate that students work mostly at the coding and running the code level and suggest that if learners knew what level they were working at and could more effectively transition across all levels, they may be more successful in their programming endeavors. A K-5 version of the framework, as shown in Fig. 2, has been used in exploratory research with younger learners and their teachers (Waite et al. 2016).

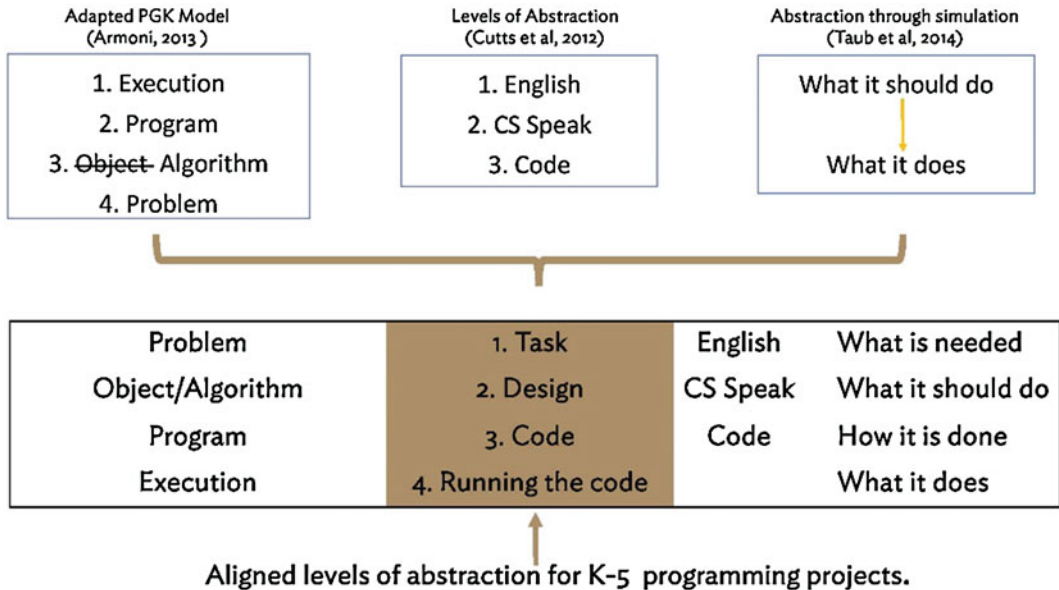

In aligning the framework to a K-5 setting several assumptions and caveats are made to support K-5 teachers. First it is assumed K-5 teachers and their pupils have less expertise in program development than those educators for whom the original frameworks relate, therefore more familiar terms have been introduced for each level. For K-5 projects, the design level also includes user interface design, algorithm, and data structure

design. It is not expected that K-5 pupils or teachers will formally distinguish between these components in the same way that specialist computer science educators teaching older pupils might. Similarly, the boundary between the original frameworks’ problem level and the object level compared to the boundary between the K-5 task and design level is much simplified. For example, any analysis associated with requirements might traditionally sit in problem level definition for older learners; however, for younger pupils a simple task definition of a few sentences is suggested with all further analysis and design being encompassed in the design level.

Uses of Design Using the Level of Abstraction Framework

In exploratory research on uses of levels of abstraction, particularly the design level, in K-5 programming projects (Waite et al. 2017) there is indication that there may be opportunities to use design.

As an aide-mémoire to know what to code next

Design in K-5 Programming Projects, Role of, Fig. 2 Aligned levels of abstraction for K-5 programming projects. (Waite et al. 2016)

To differentiate work, by teachers annotating the design with challenges or hints and tips (such as useful code snippets)

To scaffold implementing the design as code, by pupils and teachers annotating the design with code snippets

As a contract between pupils when pair programming

As an assessment tool for pupils, by pupils self-assessing their confidence to code elements of the design

As an assessment tool for teachers, by teachers reviewing pupils' understanding of how to create and implement designs

For teachers to see what they might need to teach

To evaluate completeness and coherence of the proposed solution

In annotating designs with code snippets, learners are transitioning between the design and code level. Similarly, by working with a physical design artifact learners' attention is drawn to this

level of abstraction as they are overtly working at the design level.

Research is ongoing to discover whether early results are generalizable across a wider population of teachers. However, based on initial findings it seems that some teachers are using design in novel and interesting ways to support pupils learning to program.

A Simple Mat Design

Figure 3 shows an example design for the task "Make a James and the Giant Peach story mat for our programmable toys and some route challenges for your friends (don't forget the answers too)." Young pupils might have their challenges recorded as sound clips or scribed by adults. In recalling the settings and characters to make the mat they are consolidating their literacy work in computing lessons. The teacher might demonstrate how to create a mat and show how to

include just a sketch of each image, explaining that lots of detail is not needed. This is an example of modelling abstraction. She also might model changing her ideas as she starts the creation of the actual mat, showing that design can change. By including an “avoid” or “spin on” requirement in an example challenge she can show how to make a more complex solution algorithm and how to decompose a route into parts.

Using Labelled Diagrams and Storyboards for Designs

For the task “Using Scratch, create a simple animation of your favourite things for your next class

teacher” a labelled diagram and storyboard has been used for the design, as shown in Fig. 4. The labelled diagram shows the main characters and gives opportunity to discuss what will be a sprite and what will be the background. The storyboard shows the animation over time. The teacher can demonstrate how to annotate the labelled diagram with the word “sprite” for each of the objects she chooses to be a sprite and discuss meaningful names for each sprite. Similarly, she can ask pupils to add the commands they think they might need to code the design. She can differentiate work by annotating the design with code snippets for those pupils who need extra help. For self-assessment pupils can add an indication of their confidence to implement each code

snippet, for example by highlighting with a red, yellow, or green pen. The teacher can then review the annotations and see what needs to be taught.

Using Concept Maps for Designs

As shown in Fig. 5, a concept map has been used for the design of the task “Using Scratch, create a game to help teach road safety for a national competition.” Different design types may be more suited to a genre of programming projects. For example, games often have rules that persist over time, such as how to control the movement of characters or how to keep score. Concept maps may be more suited to projects with rule-based algorithms or for learning scenarios requiring easy addition of extra detail as the projects develop. For example, learners who prefer to create programs “bottom-up,” that is exploring and building a solution through re-mixing and bricolage, need a design artifact that can grow and change with their

ideas. Similarly, learners who like to investigate each aspect of their program in much detail before moving onto the next may prefer concept maps, as these are not constrained by the size of a story-board box.

To differentiate the process of design the degree and type of support offered to learners can be varied. The teacher can provide most support by working with a group of pupils to create a team design artifact. She can provide a precreated design for other pupils to remix and amend and ask the more confident to work in pairs. Similarly, as the design is then used to support a move to coding, she can ask more experienced learners to peer assess other pupils’ code annotations and provide help cards of common code patterns.

The teacher might mark designs and further differentiate work by adding extensions, such as requesting the addition of inputs and outputs such as using a Makey Makey. When modelling using the design to support coding, the teacher might show how to tick off items implemented, and how

Design in K-5 Programming Projects, Role of, Fig. 5 Game design example

to debug as coding progresses, showing how to choose what to implement next. For example, implementing all the code for one player before adding the second player code and thereby learning from this first pass. Targeted tasks might be used to teach how to create and use designs, such as spot the difference on example designs, completing partially made designs, matching example designs to code, matching designs to tasks, comparing different annotations of code snippets for the same design, debugging designs, quick coding activities from partial designs, reverse engineering designs from code.

Drawbacks of Using Design

There are potential drawbacks from using design in K-5 programming projects. A significant risk relates to motivation and pupils' expectations of the process of programming. Some pupils may expect to start coding as soon as they are presented with a programming activity. These learners could feel demotivated and frustrated if they are required to "slow down," think ahead and create a design before they code.

Another issue might be that if pupils are asked to invest time on a detailed design, they may then be reluctant to change and develop their ideas. This can stifle creativity.

Some learners favor a bricolage approach (Turkle and Papert 1990) when creating programs, using personal experience of trial and error, tinkering, to explore what commands do, and develop an understanding of what might be achieved. In this "bottom-up" approach, as shown in Fig. 6, some programmers will have a conscious idea of what they want to make, others will not, but both can benefit from serendipitous discoveries. There is risk that design might stifle such playful engagement, reduce assimilating and accommodating experiences and constrain development of logical reasoning skills. Using design may suit learners who favor a "top-down" planning approach rather than "bottom-up" working.

However, there appears to be evidence that novice and expert programmers may take a mixed approach, switching between "top-down"

Design in K-5 Programming Projects, Role of,
Fig. 6 A 'bottom-up', bricolage or tinkering approach to programming

and "bottom-up" as and when needed. In this mixed scenario programmers sometimes plan, consciously designing and thinking ahead, and at other times explore and tinker. They switch between approaches based on their knowledge of the problem in hand, experience in the programming language, and confidence level. Which design processes and design artifacts are best suited to "top-down," "bottom-up" and mixed approaches in K-5 programming projects is, as might be expected, something that requires further research.

Comparing Industry Practice to Learning to Program in School

When designing, requirements are considered, constraints accounted for, ideas are generated, alternative options evaluated and choices made. In commercial computing scenarios, a wide range of requirements are fed into the design process including user requirements, audit and regulatory standards, program performance, system maintenance, and future needs. When first learning to design, younger learners will focus on a much-simplified subset of requirements. K-5 pupils will focus on the purpose of the thing to be created and the needs of the person who will be using their

finished product. Some learners might also consider criteria related to user interface design, how easy it is for others to understand their design, reuse of components and ease of change of their design, and even algorithm efficiency.

In professional IT projects, hundreds of developers might work on projects spanning years with vast amounts of money being spent on producing complex products such as banking systems and automated factories. In school settings K-5 learners might work independently, in pairs or small groups. Competing for precious teaching time, in a packed curriculum, these projects are likely to be completed in 4 to 6 hours over a 6-week school half-term.

Methodologies have been developed to manage commercial projects. Notable examples include the waterfall method and the agile methodology. Very simply put, the waterfall methodology requires the design for the whole project to be considered before coding starts whereas in the agile methodology the project is broken down into parts, where each part is designed, coded, and implemented before moving on to the next part (Cockburn 2002). The process young learners follow to manage their project is not likely to be the same as that used in industry, as pupils are learning about programming and design as well as using design to create a program. They are developing competencies through a design learning path, which incorporates exploration as well as design (Schulte et al. 2017). Stages in a design learning path can include asking questions, collecting ideas, exploration, decomposition, documentation, discussion, developing underlying skills, sharing, and points for self-assessment. Teachers might explicitly demonstrate the process of design and create exemplar design artifacts. They could include targeted tasks to scaffold learners' progression in design, or teachers may allow learners to develop their understanding of the process of design and design artifacts through exploration and tinkering.

In commercial projects, the design artifacts created vary according to the methodology used. Project management software is likely to be used with formal models of requirements, processes, and data structures being created. For young

learners, the design artifacts will be far less formal and may be verbal, written, or drawn.

Irrespective of what design process is followed, and what artifacts are created, design transitions the programmers' understanding of the task to a level of understanding at which they can write code. A physical design artifact, such as a storyboard or concept map, provides a route map and aide-mémoire, for a young programmer. It decomposes the design into meaningful chunks that novices can use to scaffold the process of converting this understanding into code.

Conclusion

Design in K-5 programming projects is the process of creating an understanding of a goal such that the young developer can implement that understanding as code. Some learners will follow a design process, where they think ahead, perhaps designing the whole of the product they intend to make before starting to code. Others may think to design a few parts at a time, and some may work serendipitously, evolving code as they explore with no attention to design. Typically, processes are either "top-down," creating and using a plan, or "bottom-up," exploring and building from the code. It is likely that most novice programmers will use a mixed approach, switching between "top-down" and "bottom-up" as they have ideas, work on one part at a time, learn about the task and software being used, explore, and try things out.

In primary school settings, the design process is often happening inadvertently and is likely not to be written down or retained. Design can be facilitated through an ongoing thought process which is not articulated or recorded in any way, through a physical unplugged activity acting out an event or process, or through a transient discussion. Where design is explicitly considered it is likely to be facilitated through creating drawings and written notes. Design artifacts such as storyboards, concept maps, and labelled diagrams can be developed and used. Within the design artifact, algorithms, steps, or rules that work things out or make things happen, may be depicted. Algorithms might be represented by the

simple numbering of events, a jotted rule, or even a flowchart.

Design is likely to be encountered by K-5 pupils when they tackle programming projects. Within the timeframe of the project, learning through and about design may be accomplished through a range of activities. What strategies and techniques teachers are using to teach such projects, and what approaches are most effective is not clear. However, several studies have suggested that a blended learning approach might be effective in teaching programming. Blended learning includes targeted tasks such as reading and debugging activities, teacher demonstrations, guided exploration, tinkering, using and remixing programs, creating new projects, and incorporating computational thinking.

Despite a lack of research into the use of design in primary programming, using planning to help emergent and struggling writers to learn to write has a long history of investigation that evidences the positive impact planning has on pupil self-efficacy, self-regulation, and quality of work. Common writing planning techniques such as creating and using storyboards, concept maps, and labelled diagrams may provide familiar tools for primary teachers to start to incorporate design in programming projects. Similarly, the Engineering Design

Process, used by some teachers when teaching Design and Technology, provides a “top-down” ready-made design process which has been incorporated as a simplified version in some robotics and programming curricula.

Educators make choices when creating primary programming learning activities, including choosing the objectives to be learned, expected pupil progression, differentiation techniques, assessment approaches, type of pupil involvement, hardware and software to be used, learning frameworks and models, teaching strategies and techniques, the genre of the activity, the design process, and whether design artifacts will be used. Figure 7 shows a subset of these choices that are particularly pertinent to the role of design in programming.

A learning framework that is particularly significant for the teaching of programming is the K-5 levels of abstraction framework (task; design; code and running the code). It has been proposed that if learners know what level they are working at, and if they can transition between the levels, they may make more progress in programming. Early research into the use of the levels of abstraction framework with primary teachers indicates that teachers are using levels, particularly the design level, in novel and interesting ways. By

Design in K-5 Programming Projects, Role of, Fig. 7 Aspects of design in K-5 programming activities

annotating designs with code snippets, learners are being scaffolded to move between the design and code level. Also, using a physical design artifact draws learners' attention to the level they are working at. The design artifact is also being used as a contract for pair programming as well as by teachers to know what needs to be taught next. Design annotations are also being used to differentiate work, and the design artifact is also used for pupil assessment and self-assessment. Perhaps most importantly design artifacts are being used to gather ideas and act as an aide-mémoire during implementation of those ideas to support learners' independence and self-regulation much in the same way that planning is used to support primary classroom writing.

There appear to be opportunities to build upon teachers' expertise and pupils' experience of "planning to write" in "designing to program." However, what design process and design artifacts are currently being used in classroom programming lessons is not clear. Similarly, research on pedagogy for teaching design in programming projects is limited and requires extension to younger pupils in classroom settings, and most importantly further research is needed to discover the effectiveness and impact of including design in K-5 programming.

Introduction

This entry examines the design process required for developing assessments within blended learning scenarios. Furthermore, it examines how practitioners in higher education can be supported to develop their understanding of assessment and how to design assessments into their teaching. The focus is specifically on blended learning scenarios where the expectation is that learning will be achieved through a mix of face-to-face and online interaction. However, as blended learning is a relatively broad term that may incorporate situations that are predominantly face-to-face or predominantly online, many of the principles will also apply across a broad range of learning situations. The entry draws on findings from analyzing the needs of students and lecturers and common issues relating to access to online educational resources across a partnership of Indian and European universities involved in the EQUAL Project (E-QUAL Enhancing Quality, A.a.G.o.U.E.i.I 2017). The project addressed a range of subject areas to develop design processes and

implement teaching and learning resources and activities for use in various blended learning scenarios (Webb et al. 2017). One benefit of drawing on this project is that the considerations in this study ranged across needs of students from different backgrounds and contexts as well as institutions with different infrastructure provisions. Therefore, our analysis has fairly broad considerations and applications.

In this entry, first the terminology is outlined and then important perspectives on assessment, in relation to the needs of blended learning scenarios are analysed. Then considerations are examined regarding who or what is the assessor: the teacher, the student, their peers, or technology. A brief overview of possible influences of changing assessment practices in higher education is provided. Next, the assessment design considerations identified as being essential for blended learning scenarios are outlined by examining the potential use of the revised Bloom’s taxonomy (Anderson et al. 2001) incorporated into a decision support tool to assist teachers in thinking about designing assessments (Webb et al. 2017). Finally, teachers’ professional development needs and challenges in relation to designing assessments in situations where electronic and/or online opportunities are increasing are discussed.

Terminology of Assessment

Although formative and summative assessment are commonly used terms in higher education, our experience suggests that these and other related terms have varying meanings in different contexts and confusion remains. Therefore, first, the terms are define used here are defined the issues that may inhibit effective debate in this area outlined. The term assessment itself is relatively unambiguous in that it refers to the checking of someone’s knowledge, understanding, skills, or capabilities. However, this same term is applied both to the process of checking and to the outcome of this process. Furthermore, in some educational circles, the term evaluation is used in place of assessment. In this entry evaluation is used as a broader term relating to understanding the overall

successes and failures of a course or program rather than for assessing students.

Four perspectives on assessment have been identified as shown in the model presented in Table 1 (Webb et al. 2013). This model distinguishes between a focus on the assessment process and on the results of the assessment. Furthermore, the model refers to “assessment for learning” and “assessment of learning” (Assessment Reform Group, A 2002). These terms have been used in various educational circles, in place of formative assessment and summative assessment, respectively, in order to emphasize the purpose of assessment and its relationship with learning.

Referring to Table 1, Perspective 1 is about students learning from feedback discussions and information provided during an assessment process. Perspective 2 focuses on using results of assessment for adapting teaching and learning processes. The third perspective is about the extent to which students understand the assessment process and are able and willing to engage with it. This perspective reminds us that ensuring that our assessments are accurate reflections of students’ achievements is by no means straightforward. The need to understand what will be assessed and how the assessments will be conducted becomes particularly significant when students are learning not only from the materials and teaching sessions that lecturers provide but from a broad range of online opportunities not necessarily recommended by the lecturers, for example, MOOCs that have become a significant and controversial issue in higher education provision (see, e.g., Zheng et al. 2018). Perspectives 1,

Designing Assessments for Blended Learning Scenarios, Table 1 Four ways to think about assessment (Webb et al. 2013)

	PROCESS focus	RESULTS focus
Assessment Flearning	Perspective 1 Feedback discussions and information	Perspective 2 Improvement decisions
Assessment OF learning	Perspective 3 Degree of engagement with/understanding of process	Perspective 4 Value judgments

2, and 3 are all key elements of formative assessment, which, by definition, supports students' learning and may be carried out by teachers, peers, and/or students on themselves (self-assessment). Perspective 3 is important both for formative and summative assessment because, in order to generate valid assessment information, students need to understand the assessment process and engage with it. Perspective 4 is about making summative judgments for purposes of grading and accreditation. Clearly such judgments are important and necessary at transition points between elements of a program of study and at the end.

Historically, evidence suggests that students fail to attend to feedback comments when given grades (Butler 1988) and confusion regarding the utility and need for feedback remains today. For example, despite evidence of students preferring written feedback together with annotated assignments providing explicit detail (Giles et al. 2013), studies have also shown that students do not always identify formative feedback as relevant (see, e.g., Douglas et al. 2016). Furthermore, students may not act on feedback owing to insufficient background knowledge or because the approach to feedback fails to take account of affective elements of learning (Sadler 2010). Thus, feedback involves complex processes that may be facilitated by considering not only the nature of the material and assessment but also how to engage learners in the assessment and feedback processes.

Assessors: Teacher, Self, Peer, and Technology

When designing assessments, in addition to considering the four perspectives outlined above, it is necessary to consider who/what is conducting and/or managing the assessment: students themselves, their peers, the teacher, or technology in an automated system. Enabling students to self-assess is an important goal of education because self-assessment supports the potential for students to become independent learners and to learn efficiently from the wide range of opportunities

available including online materials and activities. The ability to self-assess is also necessary for self-regulated learning (SRL). SRL, a psychological construct, refers to an active, constructive process in which students intentionally set learning goals and then plan, monitor, and regulate their cognitive, behavioral, emotional, and motivational processes in the service of those goals in order to achieve optimal learning (Pintrich 2004). The evidence suggests that one of the best ways of developing students' ability to self-assess is through peer assessment (see, e.g., Black et al. 2003).

The process of peer assessment is most productive, as well as most acceptable to teachers and students, when it involves students assessing each other's work against specified criteria and providing feedback to each other, rather than trying to assign grades (Liu and Carless 2006). For peer assessment to be a formative assessment process, the feedback needs to focus on what the student has achieved and what they should do to improve their work, together with some ideas about how to go about this improvement (Black et al. 2003). In formative feedback, dialogue forms the mechanism by which a learner monitors, identifies, and then is able to "bridge" the gap in the learning process (see, e.g., Webb 2010; Black 2015). Therefore, effective peer assessment processes become dialogic processes between students. Just as with self-assessment, discussed above, a close relationship exists between good quality peer assessment processes and self-regulated learning. The peer interaction provides opportunities for co-regulation of learning or socially regulated learning (Grau and Whitebread 2012) in which students support each other in regulating their learning.

There is also a developing body of research in support of peer assessment as a summative assessment process. There is evidence that in some fields peer assessment is just as reliable as tutor assessment (Li et al. 2016). However, the reliability and acceptability of summative peer assessment depend on the particular discipline and the credibility and capability of the person giving feedback. Furthermore, peer assessment can meet resistance from both tutors and students (Liu and Carless 2006) because in many

institutions, the expectation is for teachers to teach and make judgments about students.

Changes in Assessment Practices

More generally, assessment practices in higher education have been changing and diversifying for some years. New approaches are emerging, based on developments in digital technologies, which are increasing the range of possibilities for assessments, including increasing opportunities for personalization of assessments (Yeh 2010) and the capability for assessment to measure a broader range of knowledge and knowledge in action (Clarke and Dede 2010). For example, students can be assessed through simulations, e-portfolios, and interactive games (Gibson et al. 2007) rather than end of term exams and essays. Evidence is compelling that the nature and form of assessment have a significant impact upon the student learning experience, approaches to learning, motivation, and retention rates (Ridgway et al. 2004).

In higher education, the nature of an institution often dictates how assessment practices have been developed. For example, open and distance learning environments have emphasized the necessity for formative assessment practices. Distance education in general has been proactive in formative assessment practices out of the need to find ways to provide systematic feedback and direction to students in the absence of the immediate contact and interaction that students have enjoyed with tutors in a campus setting (Hatzipanagos and Warburton 2009). However, in both types of environments, the impact of assessment on learning can be moderated by the use of appropriate assessment methods by teaching practitioners, and practices have been supported/complemented by the use of computer-assisted learning resources (Guri-Rosenblit 2005).

Practical Considerations in Designing Assessments

Online assessments require good Internet connections, and infrastructure issues in developing

countries such as India may render online assessments unfeasible in the short term (Webb et al. 2017). Therefore, consideration needs to be given to computer-based assessments that could be delivered off-line or within a local intranet. However, our expectations are that such technical problems may be resolved within a reasonable timescale and therefore institutions also need to look ahead to consider future options.

There are also a range of tools and systems that can be used to implement assessment designs. These may range from objective testing platforms (e.g., exam-builders, Questionmark, Moodle quiz, learning management systems, assessment tools, etc.) to e-portfolios tools (e.g., Mahara, PebblePad, etc.) to authoring tools (e.g., word processors, HTML5, Storyline, etc.).

Thus, assessment decisions may be influenced by or limited by infrastructure considerations and availability of technologies or knowledge about applicability of such technologies. With this wide range of opportunities becoming available, it is especially important for assessment designs to be considered as part of pedagogical designs.

Assessment Design Within an Overall Pedagogical Design

For assessment practices to be effective in relation to the four perspectives outlined above, their place in the overall pedagogical design needs to be clear. Our view, in line with Black's (Black 2015) five-stage model of assessment in pedagogy, is that assessment considerations and actions need to be integrated in all aspects of pedagogy so that there is a match between the aims and the specific learning outcomes and the activities to support the aims and the methods of assessment. In particular, in relation to designing online materials, design of assessment must be incorporated from the initial stages of the design process just as when a teacher is planning a face-to-face lesson, the learning outcomes, activities, and assessments need to be designed to be closely aligned (Black 2015). Design decisions include the purposes of the assessment; consideration of whether the assessment is self, peer, teacher, or

automated process; practical and educational considerations regarding the mode of delivery and particular technologies to be used if appropriate; as well as what knowledge and skills are to be assessed.

A Framework for Design Considerations

Designing assessments can be supported by a framework to encourage thinking and discussion in relation to specifying learning outcomes (LOs) and designing associating learning activities assessments. A revised version (Anderson et al. 2001) of Bloom’s taxonomy of educational objectives (Bloom et al. 1956) provides a useful framework for considering learning outcomes and how to assess them. Bloom’s taxonomy was originally developed to facilitate sharing of test items between university faculties. The revised version (Anderson et al. 2001) takes account of advances in cognitive psychology and other developments since the original taxonomy was published. Whereas Bloom’s original taxonomy is arranged as a one-dimensional hierarchy with a built-in expectation of progression between levels, the revised framework is two-dimensional. There is still an indication of a hierarchy, but it is acknowledged that categories overlap and the constraint of the “cumulative hierarchy” has been removed (Anderson 2005). The taxonomy is generally represented as a table (see Table 2).

The intention is that any learning outcome can be characterized in terms of both knowledge and cognitive processes and thus can be categorized into one of the cells in the table. Using the table to examine alignment between learning outcomes, instructional activities and assessments are a key aim of the development of the taxonomy (Anderson 2005).

Based on theoretical, pedagogical, and practical considerations outlined earlier in this entry, Webb et al. (2017) developed a framework to support considerations for designing assessments. The framework was based on the revised Bloom’s taxonomy and also incorporated technical considerations, consideration of the purpose of the assessment: whether formative or summative, the assessor (peer, teacher, self, computer) and examples of appropriate assessment activities (see Table 3).

Enabling Practitioners to Design Assessments

As explained above, considerations for designing assessments include:

- The type of learning outcomes that can be considered using the revised Bloom’s taxonomy
- Who is to assess – whether peer, teacher, self, or technology
- The purpose of assessment, i.e., formative or summative
- Technical considerations such as infrastructure requirements
- Whether suitable computer-based tools are available and the particular advantages of each type of tool

Thus, the range of possible approaches and their advantages and limitations exist in a complex decision space. While teachers, rather than IT developers, are best placed to understand assessment requirements and student needs, it is challenging for teachers to be aware of the range of possibilities as well as the consequences of their

contain a set of rules about the relative advantages and limitations of various different approaches to assessment and the outcomes of using the tool, in the form of advice to the user, can be tailored in response to the user's needs as indicated by their answers to the questions. Nevertheless, because the assessment design is dependent on the large range of issues and factors discussed in this entry, it is recommended that such tools are used in professional development sessions where there are opportunities for discussion, negotiation, and collaboration.

Background of the Original Research

This entry was based on initial research undertaken in 2006 in Thailand by Kripanont (2007). It involved interviews and surveys of academics in Thai Public Universities with the aim of better understanding determinants of these academics’ acceptance and usage behavior regarding information and communication technologies (ICT). The original research was analyzed using a modified version of the technology acceptance model (TAM), along with the use of structured equation modeling (SEM), but this entry re-analyzes it in a quite different way through the use of a framework based on innovation translation and actor-network theory (ANT) (Tatnall 2013).

ICT, the Internet and Thai Universities

Thailand has a population of 69 million and Internet penetration of 43%, up from 17% in 2006 when the original research was undertaken (Internet Live Stats 2016). The Thai public university sector is supported by the government and for some years the Thai Government had a policy of supporting IT to facilitate teaching and learning processes (Government of Thailand 2001), and so in 2006, there were networks that linked all state universities around the country, offering the possibility of the Internet to facilitate teaching and learning. In 2006, Thai National Plans (National Electronics and Computer Technology Center 2001; Office of the Education Council 2004) had consistent targets aimed at the use of ICT to support continuous learning. It was seen as essential for all academics in higher education to use ICT, and especially the Internet, as most students already did so (Office of the Education Council 2004).

Technological Innovation and TAM

Exploring this research (Kripanont 2007; Kripanont and Tatnall 2009, 2011) involved the development of a modified version of the technology acceptance model (TAM) to describe the adoption of Internet technologies by academics in business schools in Thai public universities. TAM was developed from the theory of reasoned

action by Davis (1986, 1989) and assumes that a computer user acts rationally and systematically with all available information to decide whether or not to adopt this particular technology. TAM identifies determinants of acceptance and specifies causal links between the technology's *perceived usefulness* and *perceived ease of use* along with the individual's *attitude toward using technology* and *behavioral intention* in order to explain technology adoption (Davis 1986, 1989; Davis et al. 1989) (Fig. 1).

Innovation Translation (Informed by Actor-Network Theory)

Rather than focusing on just the technical aspects of an innovation and treating “the social” side of things as the context in which its development and adoption take place, actor-network theory (ANT) considers the world to be full of hybrid entities containing both human and nonhuman elements, and gives equal regard to each (Tatnall 2007). In ANT, the extent of a network is determined by actors that are able to make their presence *individually felt* (Law 1987) by other actors.

Innovation translation (Latour 1986, 1996; Law and Callon 1988) notes that innovations are often not adopted in their entirety but only after “translation” into a form that is more appropriate for use by the potential adopter. It uses these notions in an explanation of the adoption, or non-adoption of technology (Tatnall 2011).

Different Methodological Approaches to Considering the Adoption of ICT, Fig. 1 The technology acceptance model (Davis 1986, 1989)

Methodology for the Original Research

The original research employed survey methodology using semistructured interviews to gather preliminary data during an exploratory stage. Interview results were used to design a questionnaire for the next stage to collect the primary data. This was pretested, and a pilot survey conducted, but from the results of reliability, content validity, convergent validity tests, and data analysis of the pilot survey, a minor change was made to the questionnaire design before distribution (Kripanont 2007).

The questionnaires were distributed to 1,045 full-time academics, who have had some Internet experience, within 22 business schools in 24 universities in the Thai public university sector. Of these, 109 academics were on educational leave and 9 academics had no Internet experience, so the target population was 927. Because this was relatively small for a quantitative study, it was important to use all subjects in the population as targets of this survey (Sekaran 2003). After 3 months, the survey yielded a total of 455 usable questionnaires (response rate of 49%).

Research Model in the Original TAM Study

The main objective of the original research was to generate a modified model of technology acceptance, based on TAM, to best describe usage-adoption behavior by Thai academics. The generated model was expected to be both substantively meaningful and statistically well-fitting (Jöreskog 2006) and structural equation modeling was used in conjunction with the computer package AMOS. This research comprised two main stages (Kripanont 2007; Kripanont and Tatnall 2009, 2011):

1. Formulation of a technology acceptance model based on TAM and other models.
2. Generation of a technology acceptance research model that best described usage behavior of academics using the Internet in

their work. This was to make use of SEM through AMOS.

Previous Longitudinal Studies

For longitudinal studies of a new technology, behavioral intention to use was captured before actual usage behavior was measured. Venkatesh et al. (2003), for example, investigated behavioral intention and then usage behavior from the time of the initial introduction of the technology to stages of greater experience. Thus in a longitudinal study using TAM, the role of intention as a predictor of usage behavior is critical and has been well established in ICT (Ajzen 1991; Sheppard et al. 1988; Taylor and Todd 1995a).

The research model proposed for the original study was formulated on the assumption that individual reactions to use of ICT may influence actual usage and actual usage may influence intentions to use the technology (Venkatesh et al. 2003). The research model was based mainly on TAM (Davis 1989), TAM2 (Venkatesh and Davis 2000), C-TAM-TPB (Taylor and Todd 1995a, b), and UTAUT (Venkatesh et al. 2003) and specified the causal linkages between the five key concepts of: *perceived usefulness*, *perceived ease of use*, *social influence*, *facilitating conditions*, and *self-efficacy* as well as *actual Internet usage and intention* to use the Internet. The research model was formulated by theorizing these five constructs to play important roles as direct determinants of usage behavior and user acceptance.

Perceived Usefulness

In the original study, this was used as the core construct of interest and a direct determinant of usage behavior. According to TAM, it is expected that a person will use a particular technology if they believe that it would enhance their job performance (Davis 1989; Davis et al. 1989). Significantly, many models also theorized that perceived usefulness is a direct determinant of behavioral intention and usage behavior. Incidentally, *perceived usefulness* is analogous to *relative advantage* in diffusion of innovations (Rogers 2003).

Perceived Ease of Use

This is also theorized as a determinant of behavioral intention in TAM. In addition, many believe that there is strong evidence to support perceived ease of use as a direct determinant of usage behavior (Davis 1989; Gefen and Straub 1997; Igbaria et al. 1997; Szajna 1994; Thompson et al. 1991). This is analogous to *complexity* of an innovation by Rogers (2003), although in the opposite direction. Perceived ease of use is similar to effort expectancy (Venkatesh et al. 2003). Effort expectancy is defined by Venkatesh et al. (2003:450) as: “*The degree of ease associated with the use of the system.*” For the original study, perceived ease of use was considered to be a direct determinant of usage behavior because it was expected that an academic would use the Internet if they believed that the technology was easy to use.

Social Influence

In the original study, social influence was also used to determine usage behavior because it was expected that people may use the Internet if they thought that other important people *believed* they should use the technology. Social influence is defined here as “*The degree to which an individual perceives that other important persons believe he or she should use the technology/system*” (Venkatesh et al. 2003).

Facilitating Conditions

These are defined as “*The degree to which an individual believes that an organisational and technical infrastructure exists to support use of the system*” (Venkatesh et al. 2003). The empirical results indicated that facilitating conditions did have a direct influence on usage beyond that explained by behavioral intention alone.

Self-efficacy

Self-efficacy was defined in the original study as the internal notion of the individual and is related to perceived ability (Bandura 1986). With respect to ICT usage, it was anticipated that higher levels of self-efficacy would lead to higher levels of behavioral intention and ICT usage (Compeau and Higgins 1991). For this study, it was expected that self-efficacy would be a significant direct

determinant of usage behavior because the perceived ability of a person will influence them. The level of usage was expected to be related to the level of perceived ability.

User Behavior

Since an individual's stated preference to perform the activity (behavioral intention) will be closely related to the way they do behave, this assumption only applies when the behavior is under a person's volitional control (Ajzen and Fishbein 1980). Normally in Thai public universities, Internet usage by academics is by their own choice: they have volitional control, and the original research was conducted in this context.

Behavioral Intention

According to TAM, *behavioral intention* plays an important role in predicting behavior, but it is important to note that it is more predictive of behavior when individuals have had prior experience (Taylor and Todd 1995a, b). Since in this cross-sectional study individual academics already had experienced using the Internet at the time of the survey (2006), academics' behavioral intention was influenced by actual usage at this time.

Model Generation in the Original Study Using Structural Equation Modeling (SEM)

An objective of the original research was to generate a model of technology acceptance that best described usage behavior of academics with some Internet experience. This model needed to be one that was both substantively meaningful and statistically well fitting (Byrne 2001, 2006), and to achieve this objective, structural equation modeling (SEM) was used. SEM is a multivariate technique combining aspects of multiple regression and factor analysis to estimate a series of interrelated dependence relationships simultaneously (Hair et al. 2006; Schumacker and Lomax 1996). A structural equation model, or path model, depicts the structural relationships among constructs (Sharma 1996) and so SEM produces a

model of relationships among variables (Hayduk 1987). There are three important general strategic frameworks for testing structural equation models (Jöreskog 2006): strictly confirmatory, alternative model, and model generating.

1. For a strictly confirmatory approach, the researcher postulates a single model based on theory, collects the appropriate data, tests the fit of this model to the sample data, and then either rejects or accepts the model. No further changes to the model are made.
2. An alternative model approach has been sometimes used. After proposing several alternative or competing models all of which are grounded in theory following analysis of a single set of empirical data, the researcher selects one as most appropriate in representing the sample data.
3. This research was based on a model-generating strategy where the researcher could postulate and reject a theoretically derived model on the basis of its poor fit to the sample data, and then proceed in an exploratory way to modify and re-estimate the model. The idea is to locate the misfit in the model and so determine one that better describes the sample data.

By using SEM with AMOS (the software package of choice), the hypothesized model can be tested statistically in a simultaneous analysis of the entire system of variables to determine the extent to which it is consistent with the data. If fit is adequate, the model suggests plausibility of the postulated relations among variables. If it is inadequate, such relations are rejected. Despite the model being tested in each round, the whole approach is model generation rather than model testing (Byrne 2001, 2006).

Result: The Internet Acceptance Model

The Internet acceptance model developed in the original research posits three significant determinants of usage in teaching (TEACH): *perceived usefulness* (PU), *perceived ease of use* (PEOU), and *self-efficacy* (SE), and two significant

determinants of usage in other tasks: *perceived usefulness* (PU) and *self-efficacy* (SE). Social influence and facilitating conditions did not play an important role in influencing usage behavior. All direct paths (Fig. 2) between usage behavior and behavioral intention are statistically significant.

It can thus be suggested that academics used the Internet in teaching and in other tasks because of *perceived usefulness* (PU) and *self-efficacy* (SE) and noticeably in teaching. One more motivation to use the Internet was *perceived ease of use* (PEOU). This indicates that sometimes academics may not have used the Internet in teaching related tasks because they thought that there were obstacles related to using it. Self-efficacy was another important determinant, and whenever academics used the Internet, their self-confidence and perception that they were able to use the technology was significant.

An ANT Analysis of this Study

Analysis of this study was initially performed using the technology acceptance model to investigate the uptake of ICT in public universities in - Thailand. The study's sociotechnical nature, however, suggested that a reinterpretation using innovation translation informed by actor-network theory might be useful. While it is not possible to completely reinterpret an existing mixed methods study using actor-network theory as the questions that would be asked in interviews and the information obtained from the surveys would not be quite the same, there is still some value in reinvestigating the actors and interactions that may have been present (Al-Hajri and Tatnall 2011).

Whereas TAM is based on the assumption that a potential adopter is quite rational and uses information in a systematic manner to decide whether to use, or not to use this technology, innovation translation sees this quite differently. Innovation translation argues that just because a technology has been built and made available does not mean that it can automatically be assumed that organizations or individuals will want to adopt or to use

Different Methodological Approaches to Considering the Adoption of ICT, Fig. 2 Internet acceptance model – in experience and voluntary settings – five determinants (Kripanont 2007)

it, and even if an organization does adopt a new innovation, it may not use it in the way that its originator intended (Kripanont and Tatnall 2009, 2011; Al-Hajri and Tatnall 2011).

Innovation translation has the advantage of being able to easily explain examples of partial adoption, and of situations where what is actually adopted differs somewhat from what was proposed. In comparing the diffusion and translation models, Latour (1986) contends that in a diffusion model, an innovation is “*endowed with its own form of inertia and propelled from a central source.*” This enables it to move through space and time without the need for further explanation and makes it unstoppable except by the most reactionary interest groups. Once the innovation has been pointed out to people, then it should just be a matter of time before everyone, except the most immovable, recognize its advantages (McMaster et al. 1997). With the translation model, on the other hand, the initial idea hardly counts and the innovation is not endowed with autonomous power or propelled by a brilliant inventor (Latour 1996). Each potential adopter

“translates” the innovation into a form which they consider might be suitable for them. Callon (1986) suggests that the process of translation can be considered to have four aspects or “moments.”

- Problematisation – “how to become indispensable,” where one or more key actors attempt to define the nature of the problem so that they are seen as having the answer, and being indispensable to the solution of the problem (McMaster et al. 1997).
- Interestement – “how allies are locked in place.” This involves a series of processes attempting to convince and impose roles, defined in the problematisation, on other actors.
- Enrolment – “how to define and coordinate the roles.” Enrolment will follow through a process of coercion, seduction, or consent (Grint and Woolgar 1997), leading to the establishment of a solid, stable network of alliances. The innovation has now been adopted.
- Mobilization – “are the spokespersons representative?” This final step occurs as the

proposed solution gains wider acceptance (McMaster et al. 1997) and an even larger network of absent entities is created (Grint and Woolgar 1997) through some actors acting as spokespersons for others to promote adoption of the innovation (Tatnall 2009).

Whereas TAM tries to identify the perceived usefulness, ease of use, and intention to adopt by the potential adopter, ANT instead works to identify actors and their associations and interactions with other actors. Although the interview questions used in an ANT study would have been different, it is still possible to indicate how the results could be interpreted. In an ANT analysis, we begin by identifying the actors. Law (1987) describes an actor as any human or nonhuman entity that is able to make its presence *individually felt* by other actors. The actors in this case can be seen to include: the Government of Thailand, the Ministry of Education, Thai public universities, university Presidents, university academics, university administrative support staff, university technical staff, students, overseas academics, Thai Government policy, Thai e-university plans, research university plans, Thai culture, Thai language, Thai habits of reading and writing, Ministry of Commerce policy, university Councils, the Internet, university computers, and university ICT infrastructure.

The original study, and this entry’s re-analysis, was a study of innovation in investigating whether a particular technology was accepted and how this

occurred. When framed by innovation translation, the approach involves looking at how each of the actors relates to the four moments of translation. But what it is rather more difficult to now is to fully investigate interactions and associations between these actors. Some likely interactions between the main actors in this study are shown in Fig. 3.

We will now consider each of the major actors and their interactions and associations in terms of these moments of translation and speculate on how this may have occurred. As it is not now possible to go back and directly question the actors, some of this must be quite speculative.

ICT and Education Policies of the Government of Thailand

For some years, the Thai Government has had a policy of supporting ICT to facilitate teaching and learning processes (Government of Thailand 2001) and so in 2006 all Thai public universities had computer facilities and networking to facilitate teaching and learning. In 2006, Thai National Plans (Office of the Education Council 2004; National Electronics and Computer Technology Center 2001) had consistent targets aimed at the use of ICT to support learning. It was seen as essential for all academics in higher education to use ICT and especially the Internet, as most students already did so (Office of the Education Council 2004).

Different Methodological Approaches to Considering the Adoption of ICT, Fig. 3 Major interactions in university academics’ adoption of ICT

In 2006, the Thai Government's National IT Policy (IT 2010) targeted Thailand moving from being a "dynamic adopter" to "potential leader" on the basis of the United Nations' standard (National Electronics and Computer Technology Center 2001), and the government had a policy of supporting ICT to facilitate teaching and learning processes. The Thai Government's National Education Plan (2002–2016) (Office of the Education Council 2004) aimed "to develop human learning into a learning society" and to "increase knowledge leading to a knowledge-based society by development of technologies for education to support continuous human learning." The policy stipulated that by 2010 all schools would be able to connect with the IT network, and that IT would be used as part of the teaching-learning process at all levels. In accordance, the Ninth National Economic and Social Development Plan (2002–2006) stated that: "*Information Technology should be adopted to facilitate teaching and learning processes and teaching instruments to disseminate information and knowledge*" (Government of Thailand 2001).

Ministry of Education Policy and Thai Public Universities

One of the strategies of the Ninth National Economic and Social Development Plan (2002–2006) (Government of Thailand 2001) and the National Education Plan (2002–2016) (Office of the Education Council 2004) was to provide new knowledge via research. Previously, the organizational culture of the university sector was mainly teaching-oriented. But in accordance with the National Plans, each Thai university had to develop strategies to become research-oriented as this would contribute significantly more benefits to the country than being a teaching-oriented university.

The Government's *problematization* of Internet adoption by universities under the direction of the Ministry of Education probably related to what it saw as the benefits to increased national efficiency and knowledge, as well as economic benefits. Its *interessement* probably just involved a directive to the Education Ministry which meant

that they then had no choice but to be enrolled. Whether all these actors were then fully mobilized, however, is quite another matter.

Research University and E-University Plans

It was required of public and state-supervised universities to follow the National Plan and National IT policy and so they had to set a goal to become an e-university. For public universities in Thailand, the President operates the university according to the policy laid down by the University Council. University academics who acknowledge and support the research university plan will act differently to those who do not support it. It was considered that those who supported the plan would, most likely, prepare themselves for the future by trying to use the Internet to search for information for their research. On the other hand, academics who do not support this plan may concentrate only on teaching and not pay any attention to research.

The *problematization* of research university and e-university plans by universities followed directly from that of the Thai Government and probably related to what it saw as the benefits to teaching and research by adopting ICT. The universities probably did not all engage in the same form of *interessement* to support this *problematization*, but many would have done everything possible to encourage their academics to give it support and become *enrolled*. To convince its academics of the value of making use of ICT, a university could have done things like offering training and professional development activities or possibly some form of dis-incentive for not getting involved. Some academics would have become fully *enrolled* and gone on to become *mobilized* to try to encourage their colleagues, while others probably would not. Further interviews could have shed more light on this matter.

Thai Language and Culture

The Internet has had a profound impact on knowledge and worldviews through use of search engines such as Google giving millions of people worldwide instant access to a vast amount and diversity of information. The Internet represents

a sudden and extreme decentralization of information and data compared to encyclopedias and traditional libraries, but the Internet's predominant language is English. Language, according to Hofstede (1980), is one of the layers of culture and this presents a problem for those speaking the Thai language (Miniwatts Marketing Group 2006). Few databases have been developed in Thai to support higher education, meaning that typically people have to search the Internet in English to get the information they need.

Thai academics normally follow a western style in establishing the university teaching curriculum and make use of English language text books in preparing teaching materials. Although several interviewees stated that they thought that Thai language was an obstacle in using the Internet, most thought that it was not. According to the Office of Education Council of Thailand (2004), the national culture of the Thai people tends to involve the habit of not much reading and writing, and this can have an effect on Internet use (Kripanont 2007). From the preliminary interviews, one interviewee, who is expert in ICT in many Thai Government projects, suggested that this could be a problem that needs further investigation.

University Academics

How Thai university academics themselves *problematize* adoption and use of ICT is an important question, but one that would only be properly answered by more interviews. It is likely that some would *problematize* it as something very useful to their teaching and research while for others it would be just another inconvenience to make their lives more difficult. How they would respond to their university's attempts at *interessement* would also be interesting to observe. Something else about the university academics that could be investigated further is in relation to an aspect of Thai culture where differences of opinion are not usually openly expressed during meetings (Charnkit 2011). Respect for those in higher positions, such as a university President, means that following their policy is an important principle that it is natural to follow.

University students would most likely provide strong *interessement* toward academics' adoption of the Internet as they typically would have good knowledge of ICT and would be keen to see it used by their lecturers. Another interesting investigation could see how overseas academics, met at conferences, would affect Thai adoption of the Internet to communicate.

ICT Infrastructure

This nonhuman actor, if it had a voice, would probably have seen a big advantage in the value of universities making more use of ICT as it would potentially make knowledge more accessible and provide another important use for itself. Its *problematization* therefore would have been in favor of this increased use and it (or rather its proponents) would have done everything possible to convince others of this.

Conclusion

The original TAM study concluded that ICT and Internet behavioral intention were significantly influenced by actual usage, as the more experience an academic had of the technology the more significantly this affected their intention to use it in future. Perceived usefulness and perceived ease of use were each shown to have significant influence on usage behavior, particularly in teaching. Self-efficacy was also found to be another important determinant in this research as it has a strong influence on usage behavior. The study also found that social influence had no significant influence on usage, possibly because some academics already had some 6–10 years of Internet experience.

To an ANT researcher, the TAM criteria to determine adoption: perceived usefulness and perceived ease of use seem rather self-evident, not offering much in the way of explanatory power. Whereas TAM takes a fairly mechanistic approach to whether various factors are likely to have increased a potential adopter's perceived usefulness of the innovation and whether they have increased their perception that it is easy to

use, ANT makes no such prior assumptions. ANT looks instead at the interactions and associations between all the actors, making no assumptions on what these might be. ANT also looks seriously at the contributions of actors including Government policy, Thai culture and language, influences from academics in other countries, influences of the students, and the technology itself. Instead of looking only at a potential user's perceptions of the technology, innovation translation allows the possibility that this user might not want to use it in the way originally suggested: that they might want to "translate" it into another form before adoption.

This re-interpretation of a TAM study of the adoption of the Internet by academics in business schools in public universities in Thailand made use of actor-network theory and innovation translation in place of the original framework using the technology acceptance model. Of course, if an ANT approach is to be used in any research project, then ideally it would be used from the beginning of the study so that the data collection and interviews reflected the sort of questions required to approach the problem from an ANT perspective. Here, it would have been good to find out what university academics thought about the value of the Government's e-university and research university plan. It would have been good to find out more about Thai culture and language and how this might have influenced Internet adoption and use, and there are other questions that it would have been good to ask. Nevertheless, it is possible to do some "after the fact" re-conceptualization and re-analysis of the data from a TAM study to make use of an innovation translation lens.

Digital Citizenship, A Sociocultural Snapshot

Changes in society impact education systems. The term “*wicked problems*” (Rittel and Webber 1973) has been used to describe complex problems that may span economic, cultural, political, and educational domains in association with societal change. With the increase in the use of digital technologies to support learning and teaching in twenty-first century educational contexts, it has been suggested that educators and students need an increased capacity for “*wicked problem-solving*.” The sociocultural contexts students experience outside of the school environment influence the choices they make when engaging with digital technologies and the way they communicate when they do so. Sociocultural theory proposes that a range of social, cultural, institutional, and historical factors influence an individual’s behavior, thinking, and knowledge construction, and that these factors in turn influence their psychological, emotional, mental, and spiritual well-being. These multiple spheres of influence may be perceived as complementary or conflicting when considered from the young person’s perspective. The communication styles and discourse evident within their home, community, and informal social group settings will likely differ from those endorsed within the more formal settings they experience, including school. For example, the use of emoji’s (a small image used to express an emotion/idea), acronyms (e.g., LOL = laughing out loud) in a text message or email would likely be deemed unacceptable within a piece of formal writing designed to address the requirements of the school curriculum.

There are proven benefits for young people who use digital technologies. For example, digital technologies can enhance the ability for young people to communicate, collaborate, and co-create by bridging the traditional boundaries of space, time, and formal/informal settings. Digital technologies can enable the convergence of traditionally separate modes of learning. Digital technologies can foster the development of “soft” skills (e.g., experimentation, remixing, creativity), and participation within online communities can play a positive role supporting identity development. However, a range of risks have also been associated with the use of digital technologies by young people. Risks can be defined as actions that included an element of uncertainty and that can potentially have undesirable outcomes. Perceptions of risk differ, as perceptions are impacted by an individual’s values, beliefs, prior experiences/age, personal preferences, social setting, and judgment. Therefore, activities that may be perceived as being “risky” to adults may be perceived as “opportunities” by young people.

To minimize risk, there has been a global call for educational institutions to ensure students develop the dispositions, capacities, and competencies that will foster safe and effective participation within complex digital environments, within both formal and informal settings (UNESCO 2015). While schools have a legal responsibility to establish and maintain safe learning environments for students, and ensure students use digital technologies safely and responsibly within the school environment, schools also have an ethical responsibility to ensure they prepare students to do so outside of the school environment. Digital citizenship programs have been promoted as an effective way to address digital safety and responsible use in educational contexts. Unfortunately, lack of consensus defining “*digital citizenship*,” digital citizenship frameworks or how digital citizenship is best addressed within school programs has added complexity to this educational endeavor.

Multiple, contested definitions exist for the term “*citizenship*.” Simsek and Simsek (2013) suggest citizenship was historically associated with power of individuals within the process of

social decision-making, impacted by socioeconomic status, gender, age, and historical and cultural values. Mutch (2013, 52) suggests five categories to conceptualize citizenship: citizenship as *status* (i.e., legal rights and responsibilities within a political entity), citizenship as *identity* (i.e., religious, political, ethnic, and national), citizenship as the *democratic ideal* (i.e., democracy, freedom, and human rights), citizenship as *public practice* (i.e., laws, statutes, customs, traditions, and cultural norms), and citizenship as *participation* (i.e., actions that embody community-mindedness, national activism, global awareness). Tolson (2008) proposes that technology has redefined the meaning of citizenship in the digital age, defining citizenship as “a cultural idea, infused with moral meaning, encompassed by normative values and expectations that all derive from the social, historical and cultural context of the times” (Ibid., 5). Normative values can be described as the underpinning beliefs that govern what people deem to be important, informed through the social and cultural contexts they interact with, and experience, throughout all aspects of their lives.

There is also no universally recognized definition for the term “digital citizenship.” Each definition will reflect both the orientation and perception of the writer. Definitions may contain indicators that describe a variety of different things; including behaviors, skills, knowledge, capacities, conditions, challenges, choices, and/or outcomes. For example, Ribble (2010) describes digital citizenship as “the norms of appropriate, responsible behaviour with regard to technology use” (Ibid., 10), while Isikli (2015), who describes digital citizenship as a socio-technical phenomenon, proposes it is the “cultural, technological, economic and social conditions that accompany the digitalisation of citizenship” (Ibid., 25). The notion of balancing individual rights with collective responsibilities is a challenging facet of digital citizenship when considered from a sociocultural perspective. Given the centrality of values within the concept, questions arise such as; whose individual and collective values were, would be, or should be “represented” when defining these values, should

the values of individuals be deemed more important than those of the collective, and in what ways do these values differ within different cultural contexts? Rowe (1992) suggests that “moral values and beliefs are relative, and pluralistic communities are based on the fundamental principle that individuals have the right to their own values and beliefs insofar as these do not diminish the rights of others” (Ibid., 179).

When digital citizenship is considered from a sociocultural perspective, it is evident that the social groups a person participates in and belongs to, and the beliefs and traditions prevalent within these groups as situated within their cultural context, will influence how they choose to act when using digital technologies. This suggests that frameworks to support the development of digital citizenship will be most effective when they are designed for specific sociocultural contexts. The following model for digital citizenship, developed in Aotearoa/New Zealand, provides one example of a culturally located digital citizenship framework.

Digital technologies are becoming increasingly commonplace in schools and homes in Aotearoa/New Zealand and are being used by young people at an increasingly earlier age. Corresponding with this is growing concern regarding the safety, behavior, and wellness of young people who use digital devices to engage with digital content and participate within digital communities on a regular basis. In 2015, the UNESCO (United Nations Educational, Scientific and Cultural Organisation) Asia and Pacific Regional Bureau for Education reviewed the status of digital citizenship in the Asia-Pacific regions, of which Aotearoa/New Zealand is a member country (UNESCO 2015). The recommendations presented within the project summary included the need to empower young people by ensuring they learned about their rights and responsibilities through values education and the imperative to address gender equality, diversity, and cultural appropriateness in the digital age. UNESCO further advocated that digital citizenship frameworks and associated resources needed to be contextualized to provide country-specific messages and material (Ibid., 44). The report also

called for the international research community to develop a “*research agenda*” to inform interventions that were responsive and customized to regional contexts and needs.

However, digital citizenship is not currently specified within the national “*New Zealand Curriculum*” document (Ministry of Education 2007). In addition, while the USA, for example, have the ISTE standards to guide educators redesign learning and teaching for the digital age, no such standards exist to support schools across the New Zealand education system. In response to the growing imperative to address digital citizenship in a cohesive, culturally located manner, Netsafe (2016), the key independent nonprofit organization that provides support in relation to online safety in school, community, and industry contexts in Aotearoa/New Zealand, published a white paper in 2016 entitled “*From Literacy to Fluency to Citizenship: Digital Citizenship in Education.*” Within this document, Netsafe proposes that the proliferation of abstract concepts and contested definitions of digital citizenship have hindered schools’ ability to enact programs in this area. They advocate for “a consensus view” of the values, aims, and knowledge underpinning digital citizenship in Aotearoa/New Zealand to be developed, so schools can move forwards (Netsafe 2016, 3). To support this, they presented an updated digital citizenship definition and framework that acknowledges the bicultural context of Aotearoa/New Zealand. The framework specifies six guiding principles that should underpin all approaches to digital citizenship in Aotearoa/New Zealand. Importantly, each principle is also expressed in the form of a Māori value. Māori values are derived from traditional Māori beliefs, and act as lenses in the ways Māori people, the indigenous people in Aotearoa/New Zealand, interpret and experience the world. The Māori values and principles are woven together as illustrated below:

- *Ako* (all people are both teachers and learners): Young people are active agents in the design and implementation of digital citizenship, including approaches to online safety.
- *Whānau* (culturally appropriate relationships that provide a sense of belonging):

An unbounded, coherent home-school-community approach is central to the development of digital citizenship and online safety management.

- *Manaakitanga* (respect, care for others, generosity): Approaches to digital citizenship are inclusive, responsive, and equitable in design and implementation.
- *Wairuatanga* (well-being, spirituality, and intergenerational transmission): Digital citizenship in action positively contributes to well-being and resilience development enabling safer access to effective learning and social opportunities.
- *Mahi tahi* (collaboration, working together): Digital citizenship development and online safety incident management are fostered through partnership approaches, coherent systems, and collaboration (p. 4).
- *Kotahitanga* (unity, collective action): Evaluation and inquiry underpin the ongoing design of digital citizenship approached, based upon rich evidence from young people and their whanau (i.e., family) (Ibid., 4).

The Netsafe definition of digital citizenship (Fig. 1) emphasizes development in three key areas:

- *Digital literacy skills*: Skills and strategies to access technology to communicate, connect, collaborate, and create.
- *Attitudes and values online*: Attitudes, underpinned by values that support personal integrity and positive connection with others.
- *Knowledge of digital environments*: Understanding of the digital environments and contexts in which they are working and how they integrate on/offline spaces (Ibid., 3).

Netsafe propose that developing the above will enable young people to develop the “*digital fluency*” required to effectively participate in the social, economic, cultural, civic, and environmental opportunities that are increasingly available in online environments. In describing what their “ideal future” would be in response to this framework, Netsafe proposes there will be movement

Digital Citizenship, A Sociocultural Snapshot, Fig. 1 The Netsafe definition of digital citizenship. (Reprinted with permission) (Netsafe 2016)

towards *communities taking action*. If consensus can be reached, and the framework implemented across educational contexts in Aotearoa/New Zealand, the desired outcome for students situated within this sociocultural context will potentially be the realization of vision statement described in the *New Zealand Curriculum* (2007): the development of confident, connected, actively involved, lifelong learners.

In summary, schools have a legal and ethical responsibility to help students develop the digital fluency that will enable them to participate safely and effectively within the digital realm. However, given the sociocultural contexts students experience outside of the school environment will continue to influence the choices each individual makes when engaging with digital technologies, the responsibility to do so also belongs to friends, parents, family, and members of the wider community.

Introduction

Today, most people use technology not only during their formal education, in their professions or jobs but also in pastime activities in which they are motivated to produce a digital artifact (e.g., music, art, movies, apps for mobiles) or to solve problems related to their interests or hobbies. These pastime activities have a very strong creative potential. At the beginning, people usually have an idea or a problem to consider without having any notions about which technology would be needed or even if they are capable of using such technology (see [DIY](#) or [makerspace initiatives](#)).

People having such problems use technology to find solutions. In such cases, they rarely have any prior specific training and they start learning autonomously in their own time, using their own way and having in mind their own idea of digital artifacts. As a result of their creative approach, they may come up with one or more “original” solutions.

The development of young people’s skills to use digital technology is not only a school issue provided by the curriculum but also mainly derives from their day-to-day experience, interest, and needs outside the school context. Young people tend to learn from one another in their free time how to use technology, share with each other what they have done with technologies, consult

each other, and discover how to use technology and for what. Consequently, this entry aims to present growing digital literacy through creativity and autonomous learning.

Main Concepts

The DIYLab, being based on do-it-yourself (DIY) philosophy, is an example of an innovative approach to improve digital literacy through creativity and autonomous learning.

Digital Literacy

There are many definitions of digital literacy. At present, teacher educators and researchers from most of EU countries accept the concept of digital literacy defined by the EC JRC (Vuorikari et al. 2016: 9) and its five competence areas (information and data literacy, communication and collaboration, digital content creation, safety, and problem-solving). Digital literacy is rather a more complex concept. Thus, Eshet-Alkalai's (2004) conceptual model of digital literacy befits this entry. Eshet-Alkalai (2009: 93) posits that "digital literacy involves more than the mere ability to use software or operate a digital device; it includes a large variety of complex cognitive, motor, sociological, and emotional skills, which users need in order to function effectively in digital environments."

How can one develop his or her knowledge and skills to use digital technology? For many reasons, formal education is increasingly unable to provide and to offer pupils highly sophisticated and interesting activities with digital technology to contribute to their development of digital literacy. Robinson (2011) suggested that "conventional approaches tend to crush students' natural inclinations toward creative and divergent thinking." (Henriksen et al. 2016: 28). The digital literacy of young people is growing more and more out-of-school in specific activities, and this is often due to the immediate sharing of this experience among young people. "Technology changes rapidly, and it is not surprising that its integration into education still finds disappointing levels of

penetration and success" (Mishra 2012: 13–14). This is further evidenced by a number of studies among adults finding "that only about 10 per cent of learning represents formal learning in the workplace, compared with 70 per cent self- or on-the-job learning and 20 per cent peer-to-peer learning" (Grant-Clement 2017: 8).

Creativity

There are many interpretations of creativity. Warner (2000: 11) defines "creativity" as "a human act or process that occurs when the key elements of novelty, appropriateness, and a receptive audience in a given field come together at a given time to solve a given problem." Creativity involves an original approach to solving a problem combined with invention in finding a solution or producing something new. In the creative process, novelty reflects one's imagination, experiences, and thinking. The product may be aesthetically beautiful (e.g., artwork, music composition, or architecture construction) or ideationally original (e.g., Maxwell's equations). Sometimes, to be creative means to do something useful or beautiful in another way than before or than others do. Browning (2008: 213) posits "creativity involves invention, discovery, curiosity, imagination, experimentation and exploration. During the creative digital process there is a transformation from something known to something not previously known."

Digital technology offers many sophisticated tools to demonstrate and to develop our creativity. "We have seen an incredible flowering of creativity and innovation fuelled by the capabilities of such technologies. From Google to Facebook, from cloud computing to YouTube channels, digitality has altered how we live, work and connect with each other" (Henriksen et al. 2016: 27). Henriksen et al. (2016: 27) proclaim that creativity is "deeply connected to issues of technology integration, so these issues of creativity and technology can be considered in tandem." Hence, bringing creativity and literacy together can be a powerful tool in teaching and for learning, too. Nevertheless, we, the authors, wonder if technology is making us more creative.

A modern society needs educated and digitally literate people who have a creative approach to work. Unfortunately, in schools, digital literacy development is still focused on user skills. Fortunately, a key European Commission document has introduced into the concept of digital competency a requirement of creatively using digital technologies as a skill “to use digital tools and technologies to create knowledge and to innovate processes and products” and “to engage individually and collectively in cognitive processing to understand and resolve conceptual problems and problem situations in digital environments” (Vuorikari et al. 2016: 9).

Creativity with digital technology can have a different form. One of them is digital story-telling. “When students are engaged in the process of creating a digital story, they synthesise a variety of literacy skills for the authentic product: researching, writing, organizing, presenting, interviewing, problem-solving, assessing, as well as employing interpersonal and technology skills” (Baggett 2007: 180). Another example how “computing technology can be utilised to enhance our creativity within the learning process” and how digital literacy can be improved through creative projects is described by Smarkusky and Toman (2016: 35–36). They show how students of computer science or engineering “utilize technology as a means to convey their creativity, artistic design, and appreciation of the Arts. Since the creation of digital musical scores, animations and software applications share a similar development process, active-learning exercises using a variety of technologies, provide students with an opportunity to enhance learned concepts in both disciplines,” computer science and the Arts. “While experiencing the project development process, students are learning object-oriented terminology, animation frameworks, computer programming, distributed computing concepts, and principles of music theory” (Smarkusky and Toman 2016: 35). Interesting creative initiatives can also be found on the Scratch website (e.g., in programming a design of clock).

Some authors put digital literacy together with a traditional approach to literacy (as ability to read, write and communicate) only adding that

technology has been changed as how to express something in writing, from which resources we can read (locating and consuming digital content), which tools we can use for communication (Spires et al. 2012). Recently, creativity is frequently put together with the ability to create digital content. Byrne et al. (2018) show that a pedagogical model Bridge21 which consists of seven phases (setup, warm up, investigate, planning, create, present, and reflect) can be a promising approach to digital literacy development in everyone’s free time, based on his/her creativity and a strong motivation to do something completely new and interesting. “It incorporates many elements known to be conducive to teamwork; self-directedness, creativity, and positive self-driven experience.” (Byrne et al. 2018: 138).

Autonomous Learning

According to Beckert (2007), the term, “autonomy” is derived from the Greek words, “autos” (self) and “nomos” (rule or manage). “Autonomy in learning” is defined by Benson (2001: 47) as “the capacity to take control of one’s own learning.” Researchers in the field of education use different terms to explain autonomous learning. Some of these can be listed as “self-directed learning” (e.g., Ladell-Thomas 2012; McLoughlin and Lee 2010), “self-guided learning” (e.g., Welsh 2007), “self-taught learning” (e.g., Baker 2016), “self-efficacy in learning” (e.g., Livingstone and Helsper 2010), and “self-initiated learning” (e.g., Tour 2017). In this entry, the term “autonomous learning” is used.

As far as digital literacy is concerned, Ting (2015) posits that digital literacy involves autonomous learning, because autonomy in digital literacy develops when students try to resolve the difficulties they encounter when exploring the web and collecting resources for learning. Especially, online informal learning settings where learning takes places out of school, via social media, YouTube, Facebook, Twitter, wiki software, makerspace initiatives, or DIYLab, are the platforms where students are prone to become more autonomous in learning. As argued by Meyers et al. (2013: 356), “informal venues of learning and development are important spaces

where digital literacy is both employed and cultivated.” They (2013: 360) also emphasize the importance of learner autonomy in online informal settings since “informal contexts can support youth development of digital literacy by giving them problem-based challenges that support practising the application of ‘habits of mind’ to everyday situations and real-world scenarios.” McLoughlin and Lee (2010) argue how online informal learning environments enables students to direct their own learning since students select tools and collect resources to organize, create, and shape their learning content and tasks to learn more effectively and efficiently. Whereas, Lotherington and Jenson (2011) highlight that, in order to use online informal learning settings, students should be able to exchange, source, and learn from accurate material. Additionally, students should critically engage, analyze, and evaluate materials that they retrieve from the web.

Digital literacy necessitates that the user is able to self-manage his/her learning, to use and work with the technology, to exploit its functions, and to discover further functions and possibilities of technology in order to develop greater digital literacy.

DIY (Do-It-Yourself)

The concept of DIY is not totally new. It can be found when speaking of the development, for example, of amateur radio as a hobby. The DIY movement has developed and spread incrementally into different branches (technical education, art, science, etc.). It has common features: it brings together enthusiastic people (who have the same aim and interest) to solve in a creative way, interesting problems in their field and mutually to share “manuals” on how to proceed or how “you can do it yourself.”

Globally, there is a generation of DIY enthusiasts and supporters who join in various communities or networks. There is nothing that could limit activities of this generation of creative and thoughtful people; if they need to know something to be able to realize their DIY ideas, they learn from one another. DIY-ers very often use digital technology for their creative initiatives. The DIY generation visualizes stories to

document the process explaining how problems were solved to be shared as tutorials by others. Freedom to make and to create using digital technology is perceived as freedom of access, in the choice of tools and technology, and a release from reliance on specific software and hardware tools; it is using a variety of resources, making copies and sharing outcomes and methods.

Digital literacy can be improved through DIY activities cross different disciplines (technical education, Art, science, engineering, amateur radio, etc.). It has common features: it brings together enthusiastic people (who have the same aim and interest) to solve interesting problems in a creative way in their field and mutually to share “manuals” on how to proceed or how “you can do it yourself” (Černochová et al. 2018: 377). The idea of DIY can potentially contribute to further mastery in the use of digital technology and consequently improve digital literacy.

According to Kafai and Peppler (2011), it is possible also to incorporate DIY activities into programming, designing models, constructing robots, and creating manuals (tutorials) on how to do or how to learn something (for example, how to count using an abacus). Thus, DIY can potentially contribute to further mastery in the use of digital technology and consequently improve digital literacy.

The EU project DIYLab (Do it yourself in education: Expanding Digital Competence to Foster Student Agency and Collaborative Learning) implemented into school education DIYLab activities as a learning model based on DIY philosophy which is a student-centered, heuristic approach to learning and problem-solving and which implies six pedagogical principles for approaches to learning (Table 1). A key aim of DIYLab activities beyond solving a problem is to provide a manual on how to solve the problem. This “handbook” is then published in a form which can be shared with others – the best and easy to understand way is in a visible form (e.g., video, animation). The requirement to visualize a learning process about “how the problem can be solved” as a message for others follows several reasons. Firstly, visual tools are normally understood as comprehensible regardless of which

Digital Literacy, Creativity, and Autonomous Learning, Table 1 Six pedagogical principles for a design of DIYLab activities (Černochová et al. 2018)

Feature of DIYlab activity	Idea	Authors, resources
(1) To support collaborative learning	Members of DIY communities collaborate mutually	
(2) To have the characteristics of inquiry-based teaching and learning methods	DIY communities dedicate their time to original problems which have not been solved and which are different to traditional school tasks	
(3) To support transdisciplinary knowledge	To enable pupils to bring into school interesting ideas from the extracurricular environment and to create conditions for their exploration. If pupils have an interesting problem to be solved, they do not worry about which school subject it relates to	Sancho-Gil et al. (2015)
(4) To contribute to autonomous/self-regulated learning	Documenting how to proceed for others may be perceived as an author's self-reflection of his/her learning	Jocson (2012: 300)
	DIY communities enjoy finding a solution	Kamenetz et al. (2010: 20)
	"Building new tools and paths to help all of us learn"	
(5) To contribute to digital literacy improvement	"DIY youth voluntarily spend a lot of time in intense learning, they tackle highly technical practices, including film editing, robotics, and writing novels among a host of other activities across various DIY networks"	Kafai and Peppler (2011)
	To develop <i>photo-visual digital thinking skill</i> as a component of digital literacy	Eshet-Alkalai (2009: 3219) Eshet-Alkalai (2004: 93)
(6) To be connected with the curriculum	School curriculum	

languages we speak. Secondly, we are all increasingly surrounded by visual stories (e.g., YouTube, animated instructions for passengers how to behave during a flight).

An Example How Creativity and Autonomous Learning Can Contribute to Digital Literacy Development

MajaPaja is a student at a lower second school in the Czech Republic. She enjoys recording and editing digital videos and sounds in her free time and even though it was not an assignment from her school. Her father is an ICT teacher at secondary school. She produced a sound story with using only sound effects and posted her story on YouTube. MajaPaja also posted another YouTube video which she described how she produced her story with using only sound effects. Her approach

to learning with digital technology was described based on Moore's (2015) five stages of creative process (Table 2).

Inspiration: MajaPaja's father inspired her to create a sound story using digital technology without any words. She decided to compose the story in her free time as a voluntary initiative. It was for her a challenge to do something which she has never done before.

Percolation: The main problem for MajaPaja was what the story was about; she had no idea. Later, she prepared a scenario for her story-telling. In fact, the structure was particular sequences about a boy who would like to visit his girl-friend by a car (Table 3). MajaPaja did not use any particular existing story that most people know from films, books, and plays. Maybe she based her story on her experiences with specific sounds such as the voices of birds or sounds of animals.

Digital Literacy, Creativity, and Autonomous Learning, Table 2 Moore’s five stages of the creative process

Five stages of the creative process	Definition
Inspiration	Immersing oneself into their subject and aspirations
Percolation	Retaining ideas and potentially refining them before expressing them openly or presenting them in some explicit form
Preparation	Gathering information to produce the intended work
Creation	Producing the intended work
Reflection	Publishing the intended work on the Internet or displaying it somewhere to receive feedback from the others

Digital Literacy, Creativity, and Autonomous Learning, Table 3 Scenario for a MajaPaja’s sound story

	Scenario – sound story
At home	A boy is sleeping. He is snoring. He is gaping. WC. He is preparing breakfast. He is eating. He is washing in the bathroom. He is putting on his clothes. He runs his computer and he starts to read and answer e-mails. He is chatting with his girlfriend
Car	The boy goes out on the street. The boy starts the car. Driving the car. The boy listens to music in his car. An accident: the car is broken. He is bloody
Forest	The boy is calling by mobile. He is bloody. He comes out the car. He is walking. Some sounds in the woods. Sounds of wildlife and birds. A bear. The boy is fleeing. He is losing heart. He is breathing excitedly. A duel with a bear. The boy dies
End	Phone calls. Call. Cry

Preparation: MajaPaja first generated ideas about her sound story for a scenario (Table 3) and then she started producing her sound story. For her to find sounds, there were two possibilities. The first one was to download the sound recording application to her mobile phone or the second was to browse on the internet to find available sounds. Using a bear voice means that she knew that somewhere on the Internet would be the sound of a bear. From her statement about her choice of using a bear in her sound story

shows that MajaPaja appears to be knowledgeable in retrieving audio recordings.

Creation: MajaPaja’s sound story was only based on sounds or sound effects that are typical for a particular event in the story without using any words and any verbal comments. For example, when MajaPaja wanted to portray the presence of a horse, she could use a sound of horse neighing. When she has collected all necessary sounds for her story she edited and completed her story in special software for sound editing.

Reflection: On completion of her sound story, MajaPaja published it on YouTube; not only her sound-story but also another video in which she explains and describes how she did it. She then waits for people comment on what she has done.

To summarize, in the case of MajaPaja, creativity was to compose an original sound story without copying any known stories and findings ways to record sounds where she could not download sound effects from sound effect apps. Concerning autonomous learning, MajaPaja directed her project herself. She decided what story to tell with only using sound effects and she found her resources. She organized and created a sound story herself. This finding has affirmed McLoughlin and Lee’s (2010) argument of how autonomous learners direct their learning in online information settings.

Conclusions

In the future, the formal education seems not be more and more able to provide digital literacy development for people’s whole life. “The knowledge, skills and understanding we learn as children and as young people ... at school, during training and at college or university will not last a lifetime” (SEC (2000) 1832, 2000: 7).

Therefore, **everybody should care about his/her digital literacy development** throughout his/her life because new, more complex and advanced, technology will appear and the former one will disappear and what one learnt about technology before will not be enough for the future. Everybody’s life will depend more and more on a level of his/her digital literacy. “A

lack of digital literacy increasingly implicates one's full potential of being a competent student, an empowered employee or an engaged citizen." (Meyers et al. 2013: 355) Ability to managed autonomous learning and self-motivation will be "the driving force in lifelong learning, preparing students in schools for years to come. Students should be encouraged to take an active role in the learning process." (Syslo 2004: 102). Therefore, schools should concentrate on teaching pupils to learn how to learn.

Digital literacy could be developed out of school or in formal education but increasingly thanks **to sharing experiences** with others (schoolmates, friends, siblings, etc.), in personal (face-to-face) interactions or via an online social platform. For example, YouTube can support such exchange of experiences and contribute to digital literacy development based on autonomous learning, as Tan (2013: 463) showed in her research "how the students interacted with each other in these informal spaces and the role that YouTube video content plays in community formation and supporting informal peer learning."

Even though people are not advanced in some digital technologies, they should **not be afraid of using** them. The underlying aspect in their self-confidence to use new digital technologies could be (1) intrinsic motivation and (2) the feeling to produce something useful or interesting and share it with their family or friends or colleagues. For example, adults whose digital literacy skills are critical for being able to fully participate in a society and most of them may not fully engage in digital literacy skills development; nevertheless, some of them start to be motivated to use advanced digital technology when they need to communicate with their children or grandchildren (via e-mail or SKYPE) and to share digital materials (photos, videos, etc.) with their family or friends or to publish on the internet video-recording related to their hobby (mushroom picking, aviation, modelling, knitting, etc.).

An interesting problem or an idea of what to do can significantly contribute to digital literacy development although s/he is not enough digitally literate yet or s/he does not know what software

and hardware will need to solve the problem. A **strong motivation** to solve a problem or idea to create something unusual causes s/he will master very quickly to work with software and solve his/her problem in an original and creative way. S/he learns to install new software applications or hardware and to work with them. In many cases, such problems are multidisciplinary.

Even though, autonomous learning is considered to be learning by yourself, we can see that in many cases, learners receive **some facilitation and support** from their friends and family, and all these facilitation and support led them to be more autonomous in their learning. The example with MajaPaja's story demonstrates that autonomy in her learning is not just that she is searching for information from books or online resources but she also seeks advice from other people to expand her knowledge and digital skills.

The perspective of the concept of creativity is not only to create something unique but also to include digital technology to produce something that we have not thought before. It is important to have a good idea and not be afraid to deal with it. And this is what MajaPaja has demonstrated. Autonomous learners in a process of solving problem or creating interesting ideas can improve their digital literacy.

Digital Media Boards

A digital media board (DMB) is an online, web-based tool that enables the collation, curation, and creation of digital artifacts. Accessing a DMB is straightforward, through a unique website address, which can be made public or private, depending on the intended use.

While there are an increasing number of DMBs available online, in education settings there appear to be two websites that are most popular. These are Padlet (www.padlet.com) and Lino.It (en.linoit.com).

Both tools offer similar basic functionality; however, Padlet appears to be more popular in primary schools, due its moderation and teacher-control settings.

A digital media board can be used to conduct a discussion, collaborate on a task, or collect images, videos, or documents in one place. It can also be used as a visual organizer with the flexibility to create individually or with others.

Potential Benefits of Digital Media Boards to Student Learning in Primary Schools

Several clear benefits to student learning can be identified through the educational use of digital media boards (DMBs).

DMBs are online platforms that enable students to have conversations around text-based questions, images, or videos in an *asynchronous* space. This means that discussions do not occur in real time, but instead can be added as students choose.

Classrooms, however, tend to be *synchronous* spaces. When questions are asked in the classroom, students who are confident of the answer will likely raise their hands. Teachers call on these students, while others look on, perhaps still pondering the question.

In an asynchronous space, students have time to reflect and focus on the question or problem. Students can also read the ideas of others to compare to their own beliefs and can then provide their contribution to the group.

DMBs are not always used asynchronously. Teachers may ask for immediate feedback from students while they, for example, watch an educational video. Using DMBs asynchronously, however, provides students with sufficient time to reflect and carefully construct their contribution, as a personal learning experience.

By enabling all students to have an opinion on a question or topic, DMBs provide a space in which no one voice is louder than others. These online spaces can be seen as equalizing students' voices and bringing the teacher into students' discussions. Alexander (2006 p. 6) has demonstrated that increasing students' ability to engage in the conversations and discussions of the classroom can have significant learning advantages. DMBs can support students and teachers to “transform classroom talk, increase pupil

engagement, and lift literacy standards from their current plateau” (Alexander 2006, p. 6).

Digital media boards are easy to access and to use, and this seems to have increased their popularity with teachers and students. DMBs, such as Padlet, are accessible on a wide range of Internet-connected devices, including laptops, tablets, and smartphones.

A teacher shares a link to their Padlet board with their students. Each student then opens the link and can immediately begin work. This ability to quickly bring students together online is crucial to lowering barriers to technology use in the classroom. DMBs are an example of easy to use and equitable technology resources. No matter the device, students can engage in the conversation at the same level as their peers. For schools in which bring your own device (BYOD) programs, or no technology programs, exist, this is a significant advantage of the digital media board.

DMBs enable the uploading of videos, images, and documents. Users can take photos using their mobile device and add them directly to the board. An example might be a small group project of students working to bring together a research report on the state of their local natural environment. As each member investigates and collects evidence and ideas, these are added to the DMB. On the DMB, a video of the local, polluted stream sits next to documents discovered on the local council’s environmental policy website. As the evidence is collected, each piece can be moved around the DMB to create categories. As the project grows, the categories can be easily rearranged or even deleted or merged. This flexibility positions students as leaders of their learning and encourages them to work collaboratively to develop an in-depth understanding of their topic.

The use of effective feedback in classrooms has been highlighted by much research in recent years, in particular by Hattie and Timperley (2007). From Hattie and Timperley’s (2007) meta-analyses, it was reported that formative assessment, which is undertaken to inform the next steps in learning and teaching, is a significant factor in improving students’ learning. A digital media board can facilitate the use of feedback in classrooms.

A simple DMB that either invites student feedback on a particular lesson or asks students to express their learning so far can offer teachers a better understanding to both of their teaching practice and their students’ learning progress. Teachers might use a single DMB for a learning domain that is added to over the course of a unit of study or school term. Alternatively, teachers might create individual DMBs to gain feedback on students’ comprehension of specific content areas, such as fractions or electricity or grammar usage. The ability for students to contribute multimedia to the DMB also supports them to express their learning in a range of ways, beyond traditional written methods.

Beginning with Digital Media Boards in the Primary Classroom

Designing a digital media board (DMB) is not complicated. Each DMB service does, but offers slightly different functionality and settings. These should be considered when choosing a platform for use in the classroom.

Four main factors should be considered when setting up a DMB:

Purpose

How will the DMB be used? If students access the DMB purely to read content or access a link, your choices will be different than if students will contribute to the DMB. Having a clear purpose, ideally attached to a learning outcome, will make the digital media board more useful and effective for teaching and learning.

Layout

Most DMBs will provide some layouts for participant contributions. Examples from Padlet (www.padlet.com) include:

- A list. A social media type layout where new posts appear at the top of a long vertical list of contributions.
- A wall. This layout automatically fits contributions together in an easy to read layout, much like a brick wall.

- A shelf. This layout enables the creator of the DMB to create columns with headings, under each of which specific questions, comments, or artifacts are posted.
- A canvas. This blank layout enables students to add content anywhere on the page. This is useful for categorizing or sorting activities where students might want to move items around on the page.

Access

Who will be using this DMB? Be clear about who will have access to write or contribute and who will have access only to view. Also, consider the public nature of the DMB. If it contains sensitive subjects, anonymous contributions might be most appropriate. If you wish for broader community contribution, the DMB might be open and searchable on the Internet. These settings are all configurable in Padlet and in Lino.It.

Ownership

Who will have access to create the DMB? Consider who is the principal author and how a teacher or adult supervisor might best support students' appropriate behavior online. Consider whether contributions should be moderated by an adult before appearing online.

Moderating, Managing, and Leading Digital Media Boards

While easy to use and quick to set up, teachers and students should reflect on their online safety practices in the DMB to be sure that they keep their identity and personal information private, despite interacting online. Three central concepts should be considered:

1. Students under 13 years old are not usually legally entitled to sign up for online resources. This means that if primary school students create accounts on DMBs, they may be breaching the terms and conditions of that resource. A safer, more appropriate approach

is to support younger students to engage with DMBs as a small group or whole class. Ideally, a DMB would be created by a teacher or supervising adult. Students can then add contributions to the board without requiring a user account or sign in details.

2. Teachers should investigate the moderation features of any DMBs they might use in their classrooms. This is important for modelling and teaching students about safely contributing to online spaces, particularly in the primary school years. If a student adds something inappropriate or off-topic, moderation features enable the teacher to amend or remove the item in question and have a learning conversation with the student.
3. Students should be supported to use pseudonyms or first names only in a DMB. As students contribute and engage with their peers, they need to recognize their fellow students, but they do not need to read their full names. Using a consistent pseudonym is important for working in the online space and helps hold students accountable for their actions.

Educational Uses for Digital Media Boards

A further useful feature of digital media boards (DMBs) is that students can engage with a range of multimedia resources in one online space, without losing time, or focus, transitioning between webpages and computer folders.

While layouts that include multimedia may initially appear chaotic, overlapping, multimedia board can be exactly what teachers intend when setting up DMB with multimedia. The teacher may seek for each student to contribute, in whatever format they choose, which could then be used to drive a whole-class discussion and investigation. Knowing that their individual contribution would be discussed by their classmates may have the additional bonus of bringing all students into the discussion as eager participants.

Students and teachers may also use a DMB feature called "Remake" to recreate a copy of a

board, using a board as a template to build their own version. In this way, students can move, append, or delete contributions without destroying their initial board.

Teachers may also choose to include comments on the DMB. This is a further feature of DMBs. By enabling contributors to comment on the Padlet, the original author does not have their contribution changed or deleted. Instead, others comment underneath the original item and offer advice or suggestions. This can provide an ongoing sense of ownership for students as they focus on the feedback they receive and can respond.

As students engage with their peers online in a DMB, they also have opportunities to practice appropriate digital literacies and digital behaviors in a safe, moderated space. It can be a challenge to provide primary school students with online practice spaces to rehearse these skills, as concerns about abuse and safety might arise. Students at ages 10–12 have been shown in Australia (Australian Bureau of Statistics 2016) to be engaging in digital technologies and social media at a high and increasing rate. A digital media board, moderated by a teacher or supervising adult, can offer a rehearsal space for students as they begin to engage in wider social media websites and a range of online interactions.

There are numerous ways to use DMBs in the primary classroom; the examples in the following section provide suggestions for further uses, based on teachers' experiences in the classroom.

Ideas for Digital Media Board Use in the Primary Classroom

A digital media board can be either a one-way, teacher-directed repository of learning resources or a two-way collaboratively created space. The DMBs shared in this section provide authentic examples of boards used in the primary school, with a brief description of potential uses in the primary school classroom.

A basic example of a DMB is a board created by a teacher to bring together a range of resources.

Resources are gathered on the page under general headings to support students in accessing the correct item. Student of this type of DMB cannot move items around or add comments. The links to web-based resources are live enabling students to jump in and out of the DMB as they need. Using a DMB in this way enables the teacher to provide students with a single website address. From this address, a large number of other resources can be accessed.

The background images in Padlet and Lino.It can be easily modified. This means any image can be set as the background, on to which students then post their contributions. For example, a teacher might set an image of an erupting volcano as the background. The teacher then sets up the DMB but allows students to add labels to it, demonstrating their knowledge of the topic.

Sometimes teachers choose to enable anonymous contributions so that students can contribute to a DMB without fear of being wrong and having their errors exposed to their classmates. Using the "Canvas" template in Padlet, the teacher led a whole-class discussion on the accuracy of each label and moved them as necessary.

Enabling the voice of each student to be heard in classroom discussions, the DMB can be set up to structure the conversation around specific questions or themes. A teacher can develop a DMB that frames students' discussions around key concepts or known challenges in a specific topic.

Students first add a response to a concept or question and then build on the work of others, by commenting and explaining their thinking.

Conclusion

Digital media boards are easy to use online resources that are accessible on all Internet-connected devices. These digital boards are web-based and can be customized in numerous ways to meet teachers' and students' learning needs. Whether created by students or teachers, digital media boards provide students with

opportunities to understand and deeply engage in their learning.

Introduction

Patient care requires strong expertise and professional competence. As self-care increases, patients are being admitted to hospitals with increasingly complex problems. It has commonly been reported that as many as 1 in 10 hospitalized patients are harmed while receiving care, and approximately 43 million patient safety incidences occur every year. These cause great human suffering, but their economic impact is also high; for example, medication errors cost an estimated 42 billion USD annually (WHO 2017).

The World Health Organization (2017) has emphasized patient safety as the most important measure of quality of care. Ensuring patient safety is a fundamental ethical requirement for healthcare professionals. One of the greatest challenges facing healthcare today is to deliver effective and evidence-based care in challenging and rapidly changing situations. A majority of the deaths that occur in acute or general hospitals are related to a wide range of diagnostic errors, unrecognized or unattended patient deterioration, and resuscitation issues following cardiac arrest (Soar et al. 2015). Training and skills development is one of the recommended actions for enhancing patient safety in regard to these issues. The management of such situations requires, in addition to professional skills, continuous maintenance of competence.

The ability to manage critical situations should also be regularly demonstrated. Simulation pedagogy is ideally suited for this purpose since it enables active, experiential, situated, and problem-based learning. Simulations are situations that replicate actual or probable real-life conditions or events. Traditionally, in healthcare education, simulation-based learning has been delivered in classrooms or simulation centers. Recent technological developments have made it possible to provide simulations in digital environments. Modern technology can be used to immerse and engage learners in meaningful and motivating learning experiences. Furthermore, educational organizations need to deliver deeper, active learning experiences and skill-based training that integrate technology and can be accessed anytime and anywhere (Horizon Report 2017). Digital simulations commonly focus on problem-solving, and the ability to solve clinical problems is among the core competencies of healthcare professionals. Interactive and immersive 3D simulations can be seen as facilitators of virtual experiences (de Freitas 2007); and in healthcare education and professional development, learning is often experiential in nature. In order to emphasize the current era of digitalization, this article discusses the use of digital simulations in healthcare education.

The term *digital simulation* is used in this article to refer to artifacts (software and/or hardware) that replicate decision-making processes in real-world situations through different technologies, such as mobile devices, simulators, haptic simulators, games, virtual reality, augmented reality, and mixed reality. In the following sections, the benefits of healthcare digital simulations are discussed. First, different simulation technologies used in healthcare education are described. Second, the utilization of gamification in simulations is discussed. Third, motivational aspects and psychological and behavioral outcomes of digital simulations are described from the point of view of healthcare education.

Healthcare Digital Simulations

Simulation-based learning has established its place in healthcare education at universities and

hospitals over the past two decades. It is well suited for learning clinical skills, clinical reasoning, critical thinking, collaboration, leadership, and teamwork. Simulation has a positive impact on learners' knowledge, confidence, competence, and self-efficacy (Cant and Cooper 2017). Simulation as a learning strategy has been defined as "a dynamic process involving the creation of a hypothetical opportunity that incorporates an authentic representation of reality, facilitates active student engagement and integrates the complexities of practical and theoretical learning with opportunity for repetition, feedback, evaluation and reflection" (Bland et al. 2011, 668). This definition is similar to that given by Gaba (2004, i2), who wrote "simulation is a technique, not a technology, to replace or amplify real experiences with guided experiences, often immersive in nature, that evoke or replicate substantial aspects of the real world in a fully interactive fashion." The key challenge for effective learning with digital simulations is for the learner to be both engaged and motivated. For learning to be effective in digital environments, a connection must be made between what is learned and how such learning is applied in practice (de Freitas 2007). The benefit of digital simulations is that they are virtual fields of practice providing learners with opportunities for problem-solving, skill performance, and competence assessment in a controlled setting.

Technologies relevant for simulations have been divided into three types: mannequin-based simulators, screen-based simulators, and virtual reality simulators (Gaba 2007). In the healthcare literature, a large number of concepts are used in relation to digital simulations: e.g., "screen-based simulator," "computer-based simulation," "web-based simulation," "virtual patient," "virtual reality simulation," "virtual patient cases," "virtual patient simulation," "simulation games," and "serious games." Common to all of these terms is that they model a real-world situation using computers, mobile devices, virtual reality systems, or simulators. Learning methods that reproduce reality allow healthcare students and professionals to practice and learn the key competence of their profession in an immersive and

engaging way. This is because, in these systems, the patient and/or environment are presented to the learner through two- or three-dimensional visual and audio representations.

Most computer-based simulations in healthcare are low-fidelity, text-based scenarios that have been supplemented with images and/or videos (e.g., Forsberg et al. 2011). They can be, for example, video clips of actors portraying patients in a hospital setting (e.g., Verkuyl et al. 2017). Recently, serious games have been increasingly used to support professional learning and competence development, while simulation games dominate the field of healthcare. Simulation games refer to artifacts (software) that replicate decision-making processes in 3D, high-fidelity, real-world situations. Simulation games combine simulations and game elements (see Koivisto et al. 2018). Especially in medicine, simulators and haptic simulators have long been used to develop surgical skills, such as in laparoscopic surgery. Haptic simulators recreate the sense of touch and create a more immersive learning experience. At present, virtual reality (VR) is emerging alongside computer simulations. VR is “a computer-generated simulation of a three-dimensional image or environment that can be interacted with in a seemingly real or physical way by a person using special electronic equipment, such as a helmet with a screen inside or gloves fitted with sensors” (Oxford Dictionary). The benefit of VR over computer-based simulation is that in the former, immersion is more powerful and the learner has the opportunity to totally become a part of the real patient situation. Immersion refers to learners’ experience of being drawn into the virtual world such that they feel or perceive themselves to be part of the environment. Immersion and active participation in patient care create mental models for the learner that are useful in real-life situations. Another new technology emerging in the healthcare sector is augmented reality (AR), which “is a technology that superimposes a computer-generated image on a user’s view of the real world, thus providing a composite view” (Oxford dictionary). AR has been implemented in several healthcare areas, such as laparoscopic surgery, administration of

local anesthesia, endotracheal intubation, clinical breast examination, and life-support training (Zhu et al. 2014). Mixed reality (MR) is a mix of VR and AR. VR, AR, and MR are “visualization technologies which use a brain’s inherent ability to process visual information rapidly, identify patterns, and sense order in complex situations” (Horizon Report 2017, 37).

The challenge of forming an overall picture of the current situation of training applications in healthcare is that in the literature, the terms games, simulators, haptic simulators, VR, AR, or MR are used either inaccurately or synonymously. In addition, the face, content, construct, and predictive validity of studies related to different platforms are often poorly assessed (see Arora et al. 2014), which makes it difficult to evaluate the actual benefits of certain platforms for learning outcomes. Regardless, technologies with educational applications already exist, but the challenge lies in the content: There is not yet enough learning content to integrate, especially VR and AR, sufficiently into curricula. From the point of view of patient safety, it is important that the content is evidence-based and consistent with clinical protocols. Furthermore, as stated in the Horizon Report (2017), technology and digital tools can be ineffective or even dangerous when they are not integrated into the learning process in meaningful ways. One concern is the possible drift toward technology rather than pedagogy (Bland et al. 2011); advancements in technology and educators’ enthusiasm in adopting them may displace the use of learning theories and pedagogy. Another barrier might be the complexity of new technology and equipment, which could discourage educators from using technology-enhanced learning environments. Another barrier might be trainers’ ability to manage complex new technology and equipment, which may decrease the willingness of educators to use technology-enhanced learning environments. One important factor is financial resources: At present, universities are struggling with low financial resources, and thus the benefits of every new educational method and technology are measured precisely before investing in it. However, looking to the near future, when enough quality content exists,

games, simulators, VR, and AR have the potential to become significant learning methods alongside other methods; indeed, they could even replace more traditional methods. For example, in the future, substantial resource-dependent classroom simulations could be replaced by virtual simulations conducted at learners' homes.

Gamifying Healthcare Digital Simulations

The phenomenon of gamification is pervasive, affecting media, commerce, workplaces, research, education, and health, to mention just a few. Gamification refers to the application of game design elements and game principles in nongame contexts (Huotari and Hamari 2012). Gamification is also increasingly being represented in the area of healthcare. Gamification has been exploited, for example, in health promotion, prevention, early diagnosis, therapy, and rehabilitation. However, the challenge related to gamified applications in the area of healthcare is that their benefits for clinical outcomes might not meet expectations (see Edwards et al. 2016). For example, Laver et al. (2011) found no evidence that the use of virtual reality and interactive video gaming was more beneficial than conventional therapy approaches in improving stroke patients' upper limb function.

Games and gamification are also increasingly used in professional training in healthcare. One of the reasons why gamification has been utilized in professional training is the ability of games to engage learners in the learning process. Engagement in learning is highest when concentration, interest, and enjoyment occur at the same time (Hamari et al. 2016), and learners' engagement in the learning experience can be strengthened by adding game-like features to digital simulations. For example, nursing students have expressed that in order to provide significant learning experiences, educational games need to share some of the characteristics of leisure games, such as visual authenticity, immersion, interactive 3D environments, high-quality animation and sound, and immediate, sustained, and delayed feedback

(Koivisto et al. 2018). In an educational context, it is very important to integrate specified learning goals, conflicts, rules, interactions, and challenges into game characteristics (Hamari et al. 2014). Being engaged and immersed in a game depends on how challenging it is and how skilled one is at playing it (Hamari et al. 2016). The benefit of combining games and simulations is that games can provide scenarios far more complex than those in laboratory simulations (Petit dit Dariel et al. 2013), which can in turn challenge learners to the limits of their skills. Challenging tasks enable knowledge construction (Kiili et al. 2012), while game challenges can strongly predict learning outcomes (Hamari et al. 2016). Learning is most effective when the difficulty level of the tasks and the learner's skills are in balance.

Digital simulations can benefit all learners. Studies, however, have yielded somewhat contradictory results with respect to who benefits most: those who have more experience with virtual worlds or games or those who have no previous experience. Koivisto et al. (2016a) found that nursing students who were heavy or occasional digital game players felt that they learned better clinical reasoning skills than those who did not usually play at all. Similarly, Rosser et al. (2007) found a link between video game playing and laparoscopic surgical skills and suturing skills: They found that video game skills and past video game experience (consisting of at least 3 h of play per week) had a significant impact on laparoscopic skills. Video game players make fewer mistakes and perform faster than non-players. These outcomes may be explained by the fact that those who play have more experience reading the signs of the game system than those who do not play. However, prior experience of gaming may have negative impacts on learning with digital simulations since regular gamers have high expectations for fidelity and interaction, which may be poor in virtual worlds. Additionally, if the virtual environment is unstructured and open-ended, regular gamers who are used to structured and goal-oriented activities might find it difficult to navigate (de Freitas et al. 2010). This interpretation is slightly different from that of Arora et al. (2014), who argued that the more

junior the participants are, the more likely it is that training using virtual reality models will improve their knowledge and skills.

Therefore, gamification can be thought to have positive effects on learning outcomes and thus also on patient safety and quality of care. But what is the mechanism that produces positive learning outcomes when gamification is added to digital simulations? According to Hamari et al. (2014), gamification has three main parts: (1) the implemented motivational affordances, (2) the resulting psychological outcomes, and (3) the further behavioral outcomes. The motivational affordance categories can include points, leader boards, achievements/badges, levels, story/theme, clear goals, feedback, rewards, progress, and/or challenges. Psychological outcomes often relate to motivation, attitude, and enjoyment. Behavioral outcomes in the learning context relate to learning outcomes, such as achieving learning goals, task performance, and effectiveness of learning. In the following sections, motivational affordances and psychological and behavioral outcomes are reflected from the point of view of healthcare digital simulations.

Motivational Aspects of Healthcare Digital Simulations

Digital simulations have the potential to raise learners' interest in the learning content in many ways. Learners must experience the simulation as useful for their own professional competence development. This fact is highlighted in the Horizon Report (2017), which states that real-world skills are needed to improve employment and workplace development. Learning environments in which learners can practice key competences of their profession can promote learner self-directedness toward learning material and self-motivation. Motivation psychologists Ryan and Deci (2000) stated that when three innate psychological needs – competence, autonomy, and relatedness – are satisfied, self-motivation is enhanced. They distinguished two types of motivation: intrinsic and extrinsic. Intrinsic motivation refers to doing an activity for its own sake, for the

inherent satisfaction it generates. In contrast, extrinsic motivation refers to the performance of an activity in order to attain some external outcome. In the healthcare sector, job satisfaction is often derived from the ability and competence to help patients. Thus, the motivation to perform the job well is usually intrinsic rather than extrinsic. This same motivation should be cultivated in learning, and therefore learning opportunities that mimic reality should be promoted in healthcare education.

One motivating factor is likely to be that in the area of healthcare, most digital simulation applications simulate real-life clinical situations and patients' clinical conditions. Simulations consist of patient scenarios, or stories, which are events designed around a specific clinical situation. The learner usually assumes the role of a doctor, nurse, or some other professional. The authenticity and reliability of patient scenarios are important when considering the educational value of a simulation (Koivisto et al. 2018; Forsberg et al. 2011; LeFlore et al. 2012). Solving patient scenarios requires clinical reasoning skills, which constitute an essential competency for healthcare professionals. Clinical reasoning is a logical, dynamic, and ongoing process that includes the following phases: collecting and processing information, identifying problems and issues, establishing goals, taking action, and evaluating outcomes (Lewett-Jones et al. 2010). Clinical competence is a key element in safe patient care; accordingly, healthcare professionals are expected to show a high degree of competence in clinical reasoning and must be able to use it efficiently to make decisions, often independently, in complex situations (see WHO 2017).

Another motivating factor is that digital simulations have clear goals, which often include the development of clinical reasoning skills. In digital simulations, learners develop their clinical reasoning skills through different clinical situations and patient conditions (e.g., heart disease patients in emergency departments or palliative care in hospice). Clinical reasoning requires the ability to think critically, to prioritize, and to follow treatment protocols, which in turn requires that the learning objectives and game mechanics are

integrated in such a way that the simulation replicates real clinical reasoning processes (Koivisto et al. 2018). During simulation, learners should find relevant information related to the patient's clinical condition, determine the specific nature of the patient's problem, and then treat the patient correctly. The challenge in digital simulations is that patient scenarios often require learners to use their previous theoretical knowledge and experience in patient care in order to successfully solve the scenario (Koivisto et al. 2016b).

The most obvious motivating factor in healthcare digital simulations is that they can create authentic patient-related experiences (Koivisto et al. 2018). The authenticity of patient scenarios requires realistic and challenging clinical conditions. Real-life experiences can be supported by authentic audiovisual representation. Authentic representation of clinical practice can be created by using 3D characters in a 3D environment representing the hospital ward or other healthcare setting, with authentic behavior by virtual patients and interactive medical equipment. A patient's clinical condition and any changes can be observed with the help of animations, such as patient movements, facial expressions, and gestures. Authentic sounds suggesting patients' clinical conditions direct the learner to the patient's problem, helping to prioritize actions. Another important issue regarding immersion is that digital simulations should allow the learners to interact with the patients and the hospital environment. Interactivity refers to the interaction between the learner and the virtual environment, and it enables players to see the consequences of their actions. The more effectively the interaction is enabled, the more realistic and engaging the learning experience will be. The same scenarios can be shared using various technologies, and the level of immersion will vary depending on the device used. For example, VR is more immersive than simulation games played with a browser on a computer. Immersion can be diminished if patient scenarios are not realistic, virtual patients are not lifelike, or the scenarios lack interaction. This can in turn undermine the achievement of the learning objectives and can at worst cause frustration and boredom among learners.

The special benefit of interactive high-fidelity digital simulations is that they raise and sustain motivation. One study found that even though the performance level in a simulation game group and text-based cases group was the same, the simulation game enhanced students' motivation considerably, was perceived as more complex, and stimulated students to put more effort into the cases when compared to the text-based cases students (Dankbaar et al. 2016). Learners' motivation toward digital simulation can be promoted by enabling learners to actively experiment by considering different choices and making decisions in relation to the patient's clinical condition. Working with virtual cases increases learners' self-confidence in solving clinical problems (Forsberg et al. 2011), as they are able to explore, try out different strategies, make mistakes safely, learn by trial and error, and test their competence (Koivisto et al. 2018). Thus, learners become more confident in their skills and competencies. Motivation can be added by setting time pressures and limiting permitted errors: Performing a scenario against a time limit forces learners to practice quick decision-making. This skill is required especially in acute care and in rapidly changing situations. Additionally, the scenarios can be repeated, which helps learners to internalize and automatize clinical procedures and protocols. Altogether, these factors show that the option to practice patient care by using hypothetical scenarios increases patient safety. Digital simulations also increase learners' inner sense of security because they can learn from mistakes without harming real patients (Koivisto et al. 2018; Foronda et al. 2016).

To benefit fully from digital simulation, real-time feedback on a learner's performance is necessary. The timing of the feedback is important (Botezatu et al. 2010): Learners especially favor immediate feedback on their performance (Koivisto et al. 2018). If feedback is provided only at the end of the learning situation, it may be too late. In this instance, learners cannot effectively connect the feedback with their actions. However, it is necessary to *also* receive feedback at the end of the scenario, as doing so allows learners to consider issues of cause and effect

and combine their experiences with their knowledge of patient care. To gain deeper knowledge rather than learning only from memory, getting reasoning, especially with regard to errors made during the scenario, is important. To trigger reflection on learning and personal development, digital simulations should provide immediate, sustained, and delayed feedback. Koivisto et al. (2018) reported the following feedback systems in healthcare simulation games: (1) Types of immediate feedback include correcting errors, scoring, patient reactions, in-game facilitator's comments, and the effects of success and failure; (2) sustained feedback refers to changes in patients' clinical conditions during gaming, the accumulation of scores, and documentation of players' choices in the log; and (3) delayed feedback refers to players' total scores and a description of correct performance. In another study by Buttussi et al. (2013), the game gave feedback by informing the learner about the errors made and the current patient's state, summarizing the situation and providing hints for self-correction. These abovementioned feedback systems enable learners to track their competency development, which, in turn, increases the learner's intrinsic motivation to practice more to gain the knowledge and skills needed in real patient situations.

Psychological and Behavioral Outcomes in Healthcare Digital Simulations

The use of digital simulations in healthcare education has many positive psychological outcomes and other positive effects on students' learning. Healthcare students have experienced virtual simulations to be engaging and motivating (Benedict et al. 2013; Verkuyl et al. 2017). For example, a 3D single-player serious game designed to refresh trainees' advanced life-support knowledge and decision-making skills positively engaged and motivated participants in the scenarios (Buttussi et al. 2013). Similarly, a computer-based simulation increased satisfaction among nurses in setting priorities and implementing nursing skills as a protocol (Roh et al. 2013). Students also value

digital simulations because working with cases independently prior to face-to-face lessons supports students in becoming more self-directed learners (Benedict et al. 2013). In addition, learners value working at their own pace. Individually completed digital simulations offer all learners the same learning opportunities as opposed to classroom simulation, where only some of the learners are active actors in the exercise.

One benefit of using virtual reality is that it can be an efficient method for reducing student anxiety since it provides opportunities to repeat an exercise as many times as needed to achieve an adequate level of competence. However, Cobbett and Snelgrove-Clarke (2016) found contrasting results. They found that anxiety scores were higher for students who participated in the virtual clinical simulation than for those who took part in the face-to-face simulation. Positive learning outcomes have been found when intravenous (IV) simulators incorporating virtual reality (VR)/haptic device technologies were used for practical exercises of intravenous injection (Jung et al. 2012). The simulator used haptic devices that provided a sense of resistance during venipuncture and realistic 3D photographic images via polarized glasses. The skin and vein of intravenous (IV) simulators were displayed on the monitor. Likewise, Verkuyl et al. (2017) found that similar learning outcomes were achieved in relation to knowledge, self-efficacy, and satisfaction when virtual gaming simulations were compared with traditional laboratory simulations. However, the best learning outcomes are often achieved when digital simulations are used in parallel with traditional hands-on laboratory simulation (Cook et al. 2012; Jung et al. 2012; Verkuyl et al. 2017).

Mostly, digital simulations have been used for learning cognitive skills, clinical management skills, interpersonal skills, and clinical reasoning skills (Koivisto et al. 2016a; Petit dit Dariel et al. 2013). A study conducted by Evans et al. (2015) showed that playing a mobile-accessible, case-based, online game improved pregraduate and postgraduate medical learners' knowledge in recognizing and managing sepsis. Another

study revealed that a serious game with realistic, interactive cases improved residents' complex cognitive skills but was not as effective for inexperienced medical students (Dankbaar 2017). Further, when measured objectively and when using self-assessment before training, game-playing residents have shown improved clinical competencies in emergency skills compared with residents who only read course material. However, after a 2-week training period, this advantage disappeared (Dankbaar et al. 2017).

In digital simulations, a systematic approach to following the phases of the clinical reasoning process can help students to learn clinical reasoning because simulation games provide opportunities for learning by requiring students to act and think while solving the scenarios. In simulation, the activities of collecting information and taking action require concrete actions, such as clicking the mouse when collecting information by interviewing, observing, and measuring patient data, as well as taking action by implementing nursing interventions. The activities of processing information, identifying problems and issues, establishing goals, and evaluating outcomes, on the other hand, require thinking. One of the reasons why digital simulations can be recommended for use in healthcare is their potential to exert a greater impact on knowledge retention, knowledge acquisition, and knowledge application than traditional learning methods (Botezatu et al. 2010; LeFlore et al. 2012).

Digital simulations are effective tools for gaining and maintaining skills, which is especially important in the context of life support. These skills have a significant impact on patient safety, and it is recommended that life-support skills should be practiced regularly; perhaps this is why life-support applications have been the most developed. Good learning outcomes have been achieved by using the simulation gaming platform to undertake immediate life-support training. Gaming has enhanced learners' knowledge, psychomotor skills, and decision-making skills (Cook et al. 2012). Gamified simulations can also improve healthcare students' cardiopulmonary resuscitation knowledge and skills. In

one resuscitation game, the storyline revolves around an emergency situation, represented in a 3D virtual environment, where the victim, the helper, and all the helper tools may be required in the emergency. The learner takes the role of the helper, and the mission is to save the victim by applying cardiopulmonary resuscitation actions in the correct way to obtain the maximum score. Students who used the game achieved significantly better learning acquisition scores than those following traditional classes; in addition, they performed the cardiopulmonary resuscitation protocol better (Boada et al. 2015). Similarly, a 3D serious game proved to be effective in knowledge and skills acquisition in advanced life support as well as in the retention of acquired knowledge and skills at 3 months (Buttussi et al. 2013). In that game, learners had to perform various examinations (e.g., check for pulse or monitor vital signs), communications (e.g., elicit symptoms or medical history), and treatment tasks (e.g., ask a teammate to use a defibrillator). To succeed in the game, learners had to choose appropriate tasks among several alternatives in a sequence recommended by advanced life-support guidelines.

Conclusion

All the evidence described in this article supports digital simulations as a valuable learning method for healthcare education. They can therefore be recommended for use in healthcare education alongside other methods and, in some situations, may even replace traditional methods. Implementation of digital simulations in curricula is at an early stage in universities and vocational schools. However, digital simulations are especially valuable for improving patient safety insofar as they can improve healthcare staff competence in identifying patients at risk of cardiac arrest or other severe adverse events in hospitals. Digital simulations could be incorporated as part of regular staff education but could also be used by everyday citizens to help others in need and thereby prevent suffering, loss, and disability.

Digital Storytelling in Teaching and Research

Marianna Vivitsou
CICERO Learning, Faculty of Educational Sciences, University of Helsinki, Helsinki, Finland

Synonyms

Metaphor; Narrative; Pedagogy/pedagogical purposes; Qualitative research; Visual method

Introduction

The aim of this entry is to present digital storytelling as teaching and research method and draw from findings of previous studies in order to offer an updated definition based on both essential dimensions, the activity of telling stories and the use of digital technologies. Toward this end, the term will be considered as a metaphorical noun phrase. Words can be identified as metaphors at the level of language when they display a contrast between a target domain meaning and a more basic source domain meaning; also, at the level of thought, when they display a contrast between concepts that belong to different conceptual domains; and finally, at the level of communication, when they are used as metaphors to indicate a change of perspective of the target domain of an utterance. In all these cases, a contrast or comparison is involved in metaphorical meaning. More particularly, the metaphorical twist in the noun phrase “digital storytelling” lies in the ways stories have been communicated, orally or in writing, in juxtaposition with stories communicated with the use of digital technologies. Despite the contrast, the use of technology for storytelling is nowadays popularized and, therefore, conventionalized. As a result, the metaphor is conventional as well. However, the co-text also matters, since where, why, and how a metaphor is used determine the level of novelty and the degree it constitutes an innovative use of language.

The sense descriptions of “education” in the dictionary (Oxford), for example, hardly relate the field with storytelling, despite the fact that this is a domain where stories are told on a daily basis. In this context, storytelling becomes part of a broader scenario. Within this context, storytelling in education for pedagogical and research purposes could be considered as novel metaphor. Here are two examples to illustrate potential metaphorical sense of storytelling for educational purposes.

In education, storytelling with digital technologies in schools creates a hybrid context that opens up the space for action and meaning-making for students and teachers. Within this context, learning opportunities come up both “unplanned”

and as outcomes of guided formal instruction, thus transcending conventional classroom boundaries. This way of integration of digital storytelling in education introduces informal elements contrary to the formal disciplinary tradition and offers an opportunity for communicative engagement in web-based settings where exchanges can both converge with and diverge from instructional norms. Such integration has, therefore, a non-conventional character.

In research, digital storytelling is a visual method that brings to the fore and reconstructs the narratives of the research through the analysis of the message, underlying structures and techniques, how this is conveyed to audiences, and what channels of communication are used. Considering that the focus of educational technology research is mainly on how tools are used in teaching and learning, such a shift toward the discussion and analysis of the communicative integration of technologies in the classroom indicates another nonconventional use of digital storytelling.

Considering these possible ways of application, it becomes evident that both parts of the noun phrase play a role in what different significations of digital storytelling can be.

Digital Storytelling as a Twenty-First Century Metaphor

This extended entry will draw from contemporary metaphor theory (Reijnierse 2017; Steen 2011) in order to explicate the meaning of the term, based on applications in education that use digital storytelling to frame teaching and research. To this end, I will discuss digital storytelling as a phrase where the noun (storytelling) is used metaphorically and is modified by the adjective (digital) that designates the target domain of the utterance. According to metaphor theorists (e.g., Lakoff 1993; Lakoff and Johnson 1980; Ricoeur 1978; Steen 2011), a metaphor occurs when we talk about something by means of something else and, therefore, a stretch or twist is required for sense making. This metaphorical twist involves a movement to a target domain (in this case: telling

stories) to explain what, for instance, technologically enhanced practices in the field actually mean nowadays. In this sense, “digital storytelling” is a twenty-first-century metaphor that signifies mapping of two domain areas in the meaning-making process. In this mapping, “digital” signals the comparison between the domain of technology and that of telling stories.

The sense descriptions of “storytelling” in the dictionary (Oxford) involve both traditional and contemporary notions of telling or writing stories. These descriptions point to the medium, or the channel, used to communicate the story, with illustrative examples that refer to the hero/character as an integral feature of tales, myths, and legends, and also personal narratives, political commentaries, and evolving cultural norms through mainly visual technologies. The meaning of storytelling, therefore, although metaphorical, is quite conventional, if we consider the general scope of its meaning. And yet, looking into storytelling as a whole whose parts are inscribed in different modes and, as a result, mediate the communicative event with different means changes the perspective on the metaphor and the degree of its novelty.

In oral storytelling, the communicative event involves a dialogue between a speaker and a hearer, where something is expressed and communicated to another (Kaplan 2003: 30). This is a shared dialogical experience for mutual understanding and reciprocal recognition. To this effect, the speaker produces an experience for the hearer in which the latter recognizes the intention of the former. This means that to understand the meaning of the dialogue is the same as to understand what the speaker means. To resolve misunderstandings, the speaker and the hearer can ask each other questions.

In written storytelling, the story takes a life of its own, as the meaning is no longer dependent on the co-presence of speaker and hearer. In this way, the story must be interpreted in the absence of a speaking subject or a shared dialogical situation that acts as common reference. Therefore, the meaning of the author and the meaning of the written story may or may not coincide. The difference here is that while the shared dialogue

mediates oral storytelling, it is the different forms of emplotment that mediate written storytelling. We will therefore need to consider the narrative dimension of written expression.

In a similar way, digital storytelling involves multiple modes of expression through language and other symbols and media. However, contrary to traditional visual and cinematic storytelling, digital technologies have offered the possibility for interactive ways of telling stories online through the use of web-based platforms and internet services.

A contemporary definition of digital storytelling should take into account these dimensions. In addition, if we consider storytelling to be an essential feature of education, the perspective changes. As the sense descriptions in the dictionary do not connect the words with each other, storytelling for teaching and research purposes has the potential to constitute a novel metaphor for the field of education.

In the following sections, dimensions of such novelty will be discussed.

The Narrative Dimension of Storytelling with Digital Technologies

To this end, Ricoeur’s narrative theory (Ricoeur 1978, 1992; Kaplan 2003) will be used as framework to validate the definition of the term by looking into digital storytelling as series of actions organized for pedagogical and research purposes.

Classroom Interaction as a Meaningful Whole

Education has long been characterized by sets of practices that assign the central role to the teacher and the task to orchestrate the classroom event and be the protagonist on the pedagogical stage, the basic decision maker, and handler of the bulk of talking time. Looking at the metaphor anew, if by storytelling we refer to practices that change the good old script, then the term acquires a novel meaning. The content of learning, for instance, is set by the specifications of the curriculum that the teacher has to put into practice with pedagogical means. While the teacher can choose from a repertoire of methods and techniques, the

frameworks set by the curriculum leave a restricted space for teachers to truly author the pedagogical scenario, especially nowadays when the need for standardization becomes more and more marked. As a result, the teacher's agentic action becomes limited (Eteläpelto et al. 2015). Moreover, as the use of digital technologies is part of such standardization, it is doubtful whether their integration into classroom practices constitutes a novel experience in the school. And yet, the teachers' pedagogical purposes do not only draw from the official script. They are also informed from other domains such as wider socio-political developments (Vivitsou [in press](#)), which opens up the space for teachers to contribute as essential authors of the narrative in education and develop agentic action.

As it is the case with every narrative, the story of the classroom should consist of a number of events organized in a unified whole. Digital storytelling constitutes one case of holistic approach. As such, it requires the organization of sets of tasks and activities, being the parts (or events), so that the advancement of the narrative can be achieved in a meaningful way.

One way to put the events of the story together in order to construct a meaningful plot would require recounting of the involved agents' (i.e., the teachers' and the students') actions. As a result, bringing together the agents' goals and means is needed for classroom pedagogy where all agents are contributors. Within this context, teachers and students become co-authors in digital storytelling. As actions develop, the agents develop as well. It is therefore the development of both agents that needs to be accounted for.

Such development occurs in dialogue, through the co-ordination of social (e.g., group work), symbolic (e.g., a myth), and material (e.g., mobile devices, software) tools. Dialogical practices reflect the view of development as a dynamic space of reciprocal meaning-making interaction (Macy 2016; Moll and Whitmore 1993; Thompson 2013; Zaretskii 2009). Within such learning environments, development is achieved recursively as assisted performance aiming for artifact construction. As Mariotti (2009) argues, constructing artifacts enables learners to both

build shared meanings and relate with personal understandings. In this way, the process is reciprocal and takes place at the inter- and intrapersonal level. Nowadays, the view that development can happen in interaction with a knowledgeable other is disputed. Not only can the young learner learn from the teacher and peers, but teachers can learn from their young students by observing how tasks and activities are performed, decisions are reached, meanings negotiated, and so on. While development is common for all the agents, it is purposefulness that makes it relevant.

Furthermore, it is interaction on the course of dialogical situations that makes development meaningful. In digital storytelling, dialogical situations involve face-to-face communication in the classroom where the co-presence of students and teachers is required. Such communication involves both a teacher-to-student and a student-to-student pattern. In addition to the classroom, it can also occur outside the school in natural or informal settings. In these cases, the communication event takes place in dialogue or in writing and corresponds to oral and written storytelling, which was mentioned in the previous section.

Furthermore, communication can be asynchronous, when taking place on the internet through a web-based platform or service. While in the first case language is the main mode of exchange, in the second communication it is achieved through a computer and with multimodal ways of expression. As the digital media facilitate the use of technologies of transcription, modes such as speech, moving and still image, and writing appear and are available for use. In this sense, digital stories are expressions of multimodal design (Kress 2011). As such, digital stories are themselves parts of digital storytelling and use multiple modes to make the meanings of events tangible, or, according to Kress (2011), to realize or materialize meanings.

The fact that meaning is multimodal has implications both in the way it is produced and communicated. On the one hand, the production process impacts the organizational and the material setting of the classroom. On the other hand, basic parameters of the communicative event shift toward new directions, from real-life to virtual

settings, from spoken language used for oral communication to written language used for oral communication, and so on. This means that the boundaries of what is spoken and what is written blur. Therefore, different types of choice are required for meaning production and interpretation and, naturally, not all choices are relevant. The way, for instance, a response to a question is structured in face-to-face communication does not follow exactly the same rules as a response to a question on a social network, where punctuation and emoticons are essential to make up for the absence of gestures and other body language. Linguistic expression therefore remains relevant, only in different ways. As a result, these shifts open up the space for a whole new array of topical areas to be considered in education.

One such area concerns choice itself and, to be exact, what constitutes the best choice. It is therefore timely to rethink what critical judgment means and how to achieve it in education. Choice does not apply to the linguistic domain only. Also, it presupposes the act of interpretation, which, in turn, presupposes a degree of critical thinking of how to both interpret the problem and get to its solution, and evaluate its relevance to a certain kind of reality. Choice therefore relates to the context where critical judgment is exercised. Although critical judgment is essential, it is not self-evident. Rather, it should be one primary pedagogical goal aiming to support development in relation to what the learners' needs are, as these are defined within their own reality. As choice is task-based, it depends on the task as well. The more the task is bound to subject matter, the more it applies to the reality introduced by the curriculum. On the contrary, the more the task is shaped on the basis of real-life needs, the more communicative it becomes and the closer to the learner's reality it gets.

This entry aims to define digital storytelling as a metaphor in education. To this end, it will draw from research projects of pedagogical integration of digital technologies in order to lead to sense descriptions of the term based on a discussion and analysis of the tasks around which the whole experience was organized. The tasks themselves signify the events being the parts of the whole of

the digital storytelling narrative. These relate to the actions of both teachers and students, being the agents of digital storytelling. Thus, the development of events is a correlate of task development, which, in turn, links with the development of agents. Such development is performance-based, aims for communication, and involves the use of competence in several domains. As this account focuses on the whole experience, pedagogical implementations, applications, and products (e.g., the digital stories) are examined as the inside parts, or co-text, of the digital storytelling "text." In addition, "outside" elements (e.g., who the participants are, where from, and so on), or context, are taken into account. Therefore, both co-text and context are important for a valid and reliable explanation of metaphors. To be more accurate, in this case co-text and context overlap.

Storytelling as a Metaphor in Education

The co-text is, therefore, important to the way we attach meanings and determine the degree of metaphorical novelty of terms. In contemporary metaphor theory (e.g., Steen 2011), novel metaphors add an external perspective to the target domain of the utterance, in the sense that they indicate meanings different from what used to be the norm. These are called deliberate metaphors and, in terms of communication, indicate a perspective-changing function of meaning (Reijniere 2017; Steen 2011). If, for instance, storytelling is used to refer to practices that shift the discourse in education, in terms of the ways teaching is delivered and research is conducted, with the "characters" involved taking on agentic roles, then this sense constitutes a deliberate metaphor. Considering the whole noun phrase, "digital" makes more explicit the target domain of the noun it modifies and, as such, constitutes a domain adjective.

The domain adjective can work as signal of a new metaphor or as disambiguator of meaning (Reijniere 2017). In the first case, this would mean that the noun (i.e., storytelling) of the adjectival phrase (i.e., digital storytelling) would always point to the field of education. This, however, is highly improbable. Therefore, only the second function is possible in "digital storytelling." This means that "digital" further specifies

the target meaning, contrasts with oral and written, and expands the notion of storytelling. This is a more generalized use of the term and is to some degree applied here to indicate the different communication channels for telling stories.

However, this entry will focus on the function as conventional metaphor signal that revitalizes the metaphorical meaning of the noun. In this case, the noun is a potentially deliberate metaphor. To further illustrate this point, Reijnierse (2017) offers examples of multiple metaphorical propositions where more than one lexical units are metaphor-related words. In “rebuilding governmental machine” and “throws a spanner on the Whitehall machinery,” for instance, the function of the adjectives is not novel per se. But the overall context signifies a revitalization of the metaphorical use of the noun (machine). In such cases, the adjectives work as signals of the revitalized metaphors and the nouns are identified as potentially deliberate metaphors. In a similar way, this entry will draw from empirical research on digital storytelling for pedagogical purposes and principles from narrative theory in order to discuss and analyze the innovative dimensions of the metaphor noun storytelling and bring forward digital as a practice that has the potential, not only to disambiguate between means but also revitalize contemporary education.

Digital Storytelling for Pedagogical and Research Purposes

The Research Projects: Background and Methods

In the studies discussed in this entry, multiple technologies are used systematically to create a unified and coordinated learning-for-engagement with fun experience by combining and dispersing integral elements of a fiction across multiple web-based, digital, connective channels. The digital story is one in which separate elements of a larger narrative can be experienced by different audiences through a range of technological platforms. In addition, digital storytelling draws from learner-centered approaches aiming to enable student learning through the use of connective

technologies, digital mobile devices, and language toward the production of meaningful outcomes (McGee 2015). The aim is to give students a chance to tell their own stories about the topic under discussion, highlight participatory practices, increase engagement on the topic, sustain collaborative efforts, and encourage shared learning and creativity (e.g., Lambert 2013; McGee 2015; Niemi et al. 2014; Woodhouse 2008).

The studies build on the Global Sharing Pedagogy model introduced by Niemi and Multisilta (2016) to provide a framework for learner-driven knowledge and skill building by working with peers, networking and developing digital media competences and literacies.

For research purposes, the studies involve surveys, field notes, observations, and interview data resulting from the international projects that were organized and coordinated by the University of Helsinki, between 2012 and 2014. During that period, 12–15-year-old students from Finland, Greece, and California, and later, China (2015–2016) were involved in making and sharing digital stories with peers across classrooms and countries on a web-based environment. These young people, therefore, being speakers of different languages, were in intercultural encounters online. Digital storytelling activities combined formal and informal settings, while the use of English emerged as a need to tell the story to international audiences of peers when sharing on a web-based platform. Thus, they transcended the boundaries of the classroom. To deal with the situation, the students turned to available resources, including friends, class, subject and English teachers, parents, dictionaries, and the Internet. This use of language is evidence of the young people’s agency and reflects the desire to sustain the intercultural dialogue online. At the same time, it uncovers the need to further understand the complexity of using language to communicate when social and digital technologies are involved.

For the analysis, both qualitative and quantitative methods were used. Qualitative methods were applied on students’ and teachers’ interviews, the scripts of the digital stories, and the comments the students offered on the web-based environment. During the interviews, the students’ perspectives

came forward as well as how they looked at themselves not only as students but as computer and language users as well. Also, the teachers' beliefs and attitudes about the reasoning underlying their pedagogical decisions and choices came to the fore. To analyze the data, different ways of content analysis were used (e.g., thematic and metaphor analysis) for patterns underlying the participants' speech to be traced and valid conclusions to be reached. Quantitative methods aimed to show trends in participation and measure the level of student engagement. In this way, a multi-dimensional, in-depth understanding of the digital storytelling process was aimed for.

Within this framework, Niemi and Multisilta (2016) found that technology promotes engagement and allows for student-generated stories to come up (Niemi and Multisilta 2016; Niemi et al. 2014). Student stories recount single or multiple events, while the types of stories vary depending on the background teaching approach (Vivitsou et al. 2016).

Development Through Interaction and Communication

To make digital storytelling work, the teachers introduce the use of a web-based platform to connect students across classrooms. This indicates an orientation to practices that favor blended learning in school communities through interaction and online participation. As this is a dynamic, newly introduced experience in schools, it does not only require proper connectivity and infrastructure, but also takes a comprehensive view of learning with digital technologies and entails time and effort, and different types of organization and support. Therefore, different types of action are required.

Constructing Professionalism in Action

Using web-based platforms for pedagogical purposes opens up a whole array for activities and collaborative work that aim to both structure and problematize the digital storytelling process and support student work (Vivitsou et al. 2017). This type of support is determined when the teachers plan the classroom work and design the course of

action. The complexity of digital storytelling, however, does not allow for every single major or minor decision to be made in advance or every single detail to be predicted. The teaching plan, thus, is more fluid than static and, thus, rather than predefined, teaching practices develop in-action here. This means that the teachers construct professional knowledge in-action, as while observing students performing tasks, they modify their earlier decisions. In this sense, digital storytelling is a dynamic developmental experience for teachers as well, as it allows for emergent and, thus, recursive (Kvale and Brinkmann 2009) practices in situ. Recursive practices match the current needs for flexible and adaptive teaching to guide and support students adequately through the complexities of the digital era. It also serves the need for agentic action.

In an era when the digital technologies are greatly favored by the media, the market and educational policy, whether their integration into the classroom practices is a manifestation of agency, is debatable. Eteläpelto et al. (2015), for instance, claim that although notions of autonomy and professionalism have guided education in Finland for decades, new systems of governance and monitoring, reporting, and evaluation move the profession toward more limited possibilities to practice agency. Therefore, if professional agency still exists, it should be traced in the ways technology is used in combination with the pedagogical practices, in the ways the work of teachers advances.

Supporting Student Group Work

In the digital storytelling case where students need support to manage hard learning, tasks that both structure and problematize the process are needed (Vivitsou et al. 2017). The former aim to reduce complexity by, for instance, distributing the work to groups, asking students leading questions, teaching how to edit a video, and so on. The later aim to allow students to raise questions and think deeper about the process and the content. A great deal of support is needed during class work.

To this end, the teachers introduce a range of social (e.g., group work), symbolic (e.g., a myth), and material (e.g., mobile devices, software)

tools. Such practices reflect the view of student development as dynamic space of reciprocal meaning-making interaction (Macy 2016; Moll and Whitmore 1993; Thompson 2013; Zaretskii 2009) where development is achieved recursively as performance aiming for artifact construction. As Mariotti (2009) argues, constructing artifacts enables students to both build shared meanings and relate with personal understandings. In this way, development is reciprocal and takes place at the inter- and the intra-personal level. Moreover, as they evaluate own and peers' digital stories in groups, the students develop oral, written, and digital literacies while they exchange with peers, solve problems together, give and get feedback about their strategies, and adapt them when needed. In this way, students engage actively for deeper learning.

In all schools, the teachers set up digital storytelling activities in informal settings. These include topic-related places such as a museum, the local open market, the school yard, an island to study a natural phenomenon, as well as the home. In terms of knowledge creation and skill development, student background knowledge is a significant aspect of organizing digital storytelling work. Organizing digital storytelling activities in informal (natural and technological) environments allows students to investigate the phenomenon in situ, do research with internet-based sources, and decide what aspects of the topic to study, what pictures to take, how to put them together, and so on. In this learning environment, students have choice, as they work with tasks that open up opportunities for making decisions and solving problems in interaction with peers.

In addition to devices and applications, teachers combine a wide range of tasks and activities to shoot photos and videos, and edit them with mobile cameras, cell phones, and tablets. In this way, they develop digital literacies and skills, for instance, when material devices (i.e., hardware and applications) are used for digital story creation, while both a "bring your own" and a "use the school's" approach are applied. Overall, teachers handle technical requirements and perform a seamless introduction of digital tools into the classroom with a balanced use of older and

newer technologies. However, the main purpose here is to structure the process of storytelling (Vivitsou et al. 2017), rather than raise questions about, for instance, the digital divide. Despite the fact that the multiple stages of the process and the complexity of tasks (Wass and Golding 2014) open up the space for such problematizing to occur, assistance is given priority over actual development.

Problematizing the Process

Although it is structuring the work that seems to be favored, the teachers' decisions indicate a turn toward problematizing the established school reality. One way toward this direction is the integration of principles from diverse disciplines to teach content and a movement away from a "teaching-the-subject-matter" orientation to a "guiding-for-development" approach in natural surroundings and informal settings (Vivitsou et al. 2016, 2017). In addition to rethinking of the classroom as the only viable option, the collaborative mode of work is a work pattern that is preferred by teachers in all digital storytelling classrooms across countries. Collaborative work can reduce task complexity and get the activity going, as well as cater for development through peer interaction for evaluation, negotiation of the content of the story, its structure, and so on. Therefore, it offers choice for students to work on aspects and areas that they would like to, and allows for personalized learning. As well, the teachers can observe classroom action and reflect on own decisions. In this way, collaboration is one step to take their thinking further and weigh between the need for structure and critical judgment.

In addition to common approaches and characteristics, it seems that there have been choices that can potentially mark unique teaching styles able to move the profession toward more concrete agentic action, as a counteract to the loss of autonomy the "new public management culture" has invoked (Eteläpelto et al. 2015) on the grounds of tightened accountability. To further illustrate this point, three examples will be mentioned here from the digital storytelling situation (Vivitsou et al. 2017).

One concerns a mid-career male Finnish teacher who explains when interviewed that his intention is to build a narrative and draw connections between the past and the present. More particularly, the aim to allow the students to explore what the Ice Age has influenced the evolution of the Finnish landscape and, in this way, gets a deeper understanding of history through geography in field trips and observations and a freer way to learn. A second example is about an experienced female Finnish teacher who defines herself as a constructivist and, as such, committed to finding ways that allow students to draw connections for knowledge building. For this purpose, she chooses storytelling as one way to make students' thinking visible. She does so, like a "magician in a theatre or a circus," always in search for something new. A third example concerns a female mid-career teacher from Finland who believes that the classroom needs to open up and expand its boundaries, especially now when the school becomes more and more multicultural. Intercultural encounters, therefore, using digital storytelling as teaching method seems to be a pathway for her students from diverse backgrounds getting motivated and engaged with learning. Moreover, digital storytelling is one way to collaborative practices that make schooling more democratic and less authoritative.

Although more research is needed on the matter, these choices point toward particular styles of teaching that, at the time of the digital storytelling implementation, made teaching a singular, individual work. Partnering with methods and techniques that give more choice and more voice to the student, individual stances to historically grounded teaching aiming to bring the young people's thinking to the fore through freer schooling may form the basis for bottom-up practices for a restored agency in the profession. Thus, singular, theoretically grounded choices combined with universal approaches mark the teachers' orientation in digital storytelling.

Performing Multimodal Storytelling Tasks

As we look into digital storytelling as narrative, how the classroom events develop matters. Therefore, the students' actions and how they achieve

meaning construction plays a role. In digital storytelling, meaning is made through a multiplicity of modes that present evidence of learning in different ways. Under this lens, learning results out of the engagement with an aspect of the world that is the focus of attention on-task, on the basis of the principles the individual brings to that engagement. Such engagement is thus leading to a transformation of the individual's conceptual resources (Kress 2011). Conceptual resources include both a better understanding of the object of study (i.e., the content or subject matter) and an updated sense of identity. Initiative plays a crucial role in this development.

Student Initiative

The studies discussed here show that the students developed initiative for mainly two purposes. One type of initiative emerges out of group and individual work aiming for story completion and task accomplishment (Vivitsou et al. 2016, 2017). In order to make the stories communicable, the young people turned to friends, teachers, parents, and the Internet for language and other types of support. In this way, they were able to subtitle, structure, publish, share, and comment the stories. In this way, the stories are not only testimonies of the young people's taking action, but also of the desire to sustain the dialogue in group work and with connected peers online.

While developing a sense of being storytellers, students enter a dialogue with peers where cultural characteristics show up, as, for example, when Greek student stories reveal elements that connect the historical past with the present, by drawing upon mythology and history. In this learning space, students develop an embodied rather than exclusively cognitive appreciation and display an ability to respond with new initiatives. In this sense, the students do not just carry out, but perform the task. Thus, commitment to hard work seems to be intertwined with performance. This becomes obvious through mainly three ways of student action:

By taking on a role and acting as director, script writer, narrator, and so on, student appreciation of the story-making process changes.

By entering into dialogue with peers, they act with rather than acting over others.

By acting to explore and understand better, student appreciation of the surrounding space and those found in it as well as of the process and the content of learning changes.

They also re-establish relationships with peers and develop a sense of being-in-the-world by getting involved with other people, other species, and the surrounding space, whether physical or virtual. In this sense, students do not simply enact a preassigned role, but learn and grow by changing through own efforts and encourage others to change as well (Vivitsou and Viitanen 2015). Ultimately, student initiative, embodied action, and ongoing decision making, although not in a mutually exclusive way, are related.

Intercultural Exchanges with Peers Online

Within this context, the use of English as common medium comes up “unplanned” rather than as outcome of guided formal instruction to transcend conventional boundaries. This opens up the opportunity for learners to use diverse texts from “out-of-school” domains and, thus, pushes the boundaries of formal schooling to get unsettled at the intersection of the “script” (i.e., the curriculum) with the digitally mediated lifeworld contexts (Lund 2006; Ørevik 2015). In this sense, digital storytelling is a generative device that proceeds from practice and work toward the production of artifacts and works of discourse. In other words, digital storytelling constitutes a (pedagogical) genre (Vivitsou 2016) that encompasses the ways of acting and the purposes of those who act. In terms of communicative purpose, digital stories can generate cross-cutting text types, ranging from descriptive to expository to narrative to dialogic and reflective (Ørevik 2015).

As the findings of the empirical studies show, student-generated stories can be single- or multiple-event based when they tell the story of one or several instances or aspects of a phenomenon (e.g., a historical event, a chemical reaction, etc.). When they tell the story of the young story makers’ everydayness, the stories are student-

initiated (Vivitsou et al. 2016). Both event-based and student-initiated stories use language to pass the message through. Language use mainly comes up in the form of oral expression in the speakers’ L1 (mother language) and can be preplanned (e.g., as in the case of event-based stories) or more spontaneous (e.g., in student-initiated stories). It can also come up as written speech in the shape of, for instance, subtitles (or annotations, i.e., short verbal explanations of the content of the story). Subtitles aim to summarize and provide the gist (i.e., the main idea) of the story.

Use of Language for Authentic Purposes

As students share digital stories with peers on a web-based environment, storytelling activates discussions and exchanges in the form of comments. Such interactions can offer insights into the content, the production or the purpose underlying the story, and can offer the ground for deeper reflection on these areas. The aim here is both to set and expand social relationships, and meet the pedagogical purposes.

Storytelling by using web-based platforms and the services of Web 2.0 involves social networking practices. When, for example, the young people share stories online and respond to their peers’ comments in the designated area of a web-based platform, they type capitals and post emoticons to signify gesture and other body language markers. In this way, while interaction turns become enriched through comments (Penttilä et al. 2016), semiotic markers make up for the absence of other signs of communication and introduce a contemporary popular practice into the classroom event. Emoticons are not the only symbolic system.

The story itself is based on signs and symbols, in terms of the ways storytellers represent the events, and how the characters express themselves. The young people, as mentioned above, use their L1 to communicate the message of the story. In addition, they need to use a language other than their L1, in order to share and communicate with international peers. Language can come up in the form of oral expression and can be preplanned or more spontaneous. It can also come up in the form of subtitles to summarize and

provide the main idea so that the story can make sense.

In this way, the young people are engaged in symbolic work in multiple ways. In digital storytelling, symbolic work concerns both text-based and video-based exchanges. It is, therefore, essential that future practices will consider the need to set a common “language” that does not involve the linguistic code only.

Furthermore, it becomes clear that when the young people work on the story, they already have the distant peers in mind. The distant peers are imagined. According to Norton and Toohey (2011), imagined communities can represent a reality as strong as that of learners’ daily engagement, and can have an intense impact on the learning process. Norton (2010) even argues that a lack of awareness of learners’ imagined communities could narrow the possibilities of development in that learning environment.

Identity scholars (e.g., Norton 2010; Norton and Toohey 2011; Pavlenko and Norton 2007) link imagined communities with the learners’ imagined identities, as the one assumes the other. As Norton and Toohey (2011) argue, a target (language) community is not only a reconstruction of past experiences and historically reconstituted relationships. It is a desired community offering a range of identity options and a way for learners to look to the future. Nowadays, web-enhanced encounters in multilingual settings make even more pronounced the need to consider how young people construct identities, as the fluid time-space and the lack of boundaries of the electronic medium can create ambiguities of subject positions (Kramsch 2009: 172–173).

The computer, therefore, is a window that looks through and at the world, and, as such, frames reality through the symbolic forms that appear on the screen. As a result, the young students are nowadays engaged with identity work, as they author and narrate their pathways to their audiences by using computers and digital technologies. According to Thorne and Black (2011), as diverse language-cultural backgrounds of participants intersect in heterogeneous textual inspirations, participants are engaged in symbolic work by actively contributing to a transcultural blend of

literary and popular culture fictional worlds. In this way, members of the community enter a process of interpreting one another’s work, while they author their narratives sitting behind the screens of their computers or navigating through the screens of their mobile devices.

Digital Stories for Pedagogical Purposes

When it comes to digital storytelling tasks, it is not only the digital story that matters, it is also the “about the story” or meta-story that should be taken into account. Attributing meta-features contextualizes the story and extends the digital narrative. In this sense, the digital story is part of the whole of digital storytelling, not the whole per se. Following this, the following section will focus on issues about the stories. One such issue concerns the different sets of events that the digital stories can present. Some stories focus on instances of the object of study and others present more complex plots. While the former act like zoom-in lenses of the classroom narrative, the latter build up networks of actions. In both cases, the students act as storytellers and characters. The characters of the stories can be real or fictional. As a result, different types of stories come up.

The types of digital stories (Vivitsou et al. 2016) relate to the underlying teaching approach and are categorized into: (1) subject-based digital stories, (2) interdisciplinary digital stories, and (3) student-initiated stories. The latter had an indirect connection to curricula, introducing themes and events that were interesting and important to students. The topic and perspective in subject-based stories focus mainly on a school subject, whereas interdisciplinary digital stories cross these borders. Following this initial categorization, the digital stories are reviewed from the perspective of narrative: on one end of this scale, there are stories that describe student observations on instances of a phenomenon; on the other, the stories are longer and demonstrate a tighter narrative structure.

Subject-Matter-Focused Stories

Instances of a Phenomenon These subject-specific stories present the students’ efforts to capture a particular aspect of a phenomenon, in this case a

chemical or physical one, in order to study and obtain a deeper insight into it. The production of these stories varied from rather unedited video clips to more structured ones, yet the key attribute was that they consisted only of a single scene that had been captured at once. These clips were about tasks carried out during lessons or events observed on field trips. In a sense, they were captured “in the heat of the moment” in order to document what the students considered relevant and interesting.

The possibility of filming seemed to increase student motivation when science learning was transferred to off-school sites (e.g., field trips, a chemistry laboratory, science center, etc.). In the lab, students could focus on and observe experiments very attentively through video lenses. Selecting a phenomenon and trying to understand and explain the event (e.g., a chemical reaction) to a potential audience were important parts in the students’ study process. In some cases, subject-based stories were recorded at home or during a holiday trip. When conditions permitted, stories were filmed in classroom settings (e.g., the science lab).

Multiple Phenomena-Based Stories These include clearly distinguishable clips that together form the story. In this way, they build a tighter narrative than the aforementioned instance-based stories. One of the most elaborate multiple phenomena-based digital stories about science was related to air and was captured on a field trip. This story combined different themes, which mainly enriched the curricular content taught at school. The storyteller also put significant effort in structuring and framing the scenes with relevant scientific explanations in the form of annotations (i.e., a type of subtitles that can be added during the editing process for further explanation or descriptions of the object of study). The story grouped different air-related exhibitions into four scenes. The first scene consisted of a short video clip of a scale model of Earth. The second portrayed a student testing the effects of air pressure with a pump-like device, where a weight is dropped inside a tube in order to achieve a causal effect in a tube placed next to it. As a result of

dropping the weight, a tennis ball flew up in the other tube. The third clip dealt with a hot air balloon that rose and fell. The final scene was captured during a live performance where a scientist demonstrated the space requirements of gases by inserting a straw into subliming dry ice.

Interdisciplinary Digital Stories

Most of these were multievent stories. As a single event, a story could be a picture or snapshot of the single phenomenon, e.g., a video clip from a forest. In interdisciplinary stories, the attention is placed on a series of actions. Therefore, the plot displays a more elaborate structure by, for example, introducing a conflict or reaching a climax and resolution. Interdisciplinary stories cross the borders of different subjects for production. For example, stories about myths were created during history and Greek language lessons. Overall, they build a tighter narrative and introduce fictional characters. The multievent stories focused on the following themes.

Themes from the Human Sciences These stories build a more structured narrative by recounting multiple events in the characters’ lives using dramatization (e.g., body movements and gestures) and other narration techniques to support storytelling. One example draws upon ancient Greek mythology to provide alternative versions of myths. A secondary aim is to enhance student understanding of a natural phenomenon such as season alternation during the year by drawing links with mythical explanations from ancient times.

In the story *Euro, the birth of Europe*, two narrators support action with scripts delivering the message to the international network of peers using English subtitles. Dramatization techniques are efforts to free the communication of meaning from language barriers. The storyline centers on three main characters: Zeus, Europe, and the people. In another story, the *Myth of Persephone*, oral narration pulls plot strings together and the 8-year-old storyteller alternates text slides with action to support the narrative. This filmic practice not only mimics silent movie logic, but also aims to overcome language barriers arising from the

fact that the students have just been introduced to learning the English language.

Combining Complex Themes Some digital stories presented variations of a more complex phenomenon, such as recycling. To produce the videos, the students worked together to create a plot and convey the message through the interaction in the story. Unlike the myths, these stories introduce “real-life” characters using several filmic practices. In this classroom, the students decided what kind of stories they would like to produce and what aspect of recycling they would like to explore in their videos. All stories aimed to inform and give instructions about how to recycle and, in general, were dramatized and acted. In some of these videos, one character does not know how to recycle and another advises to do that. Alternatively, a character seeks information on ways of recycling from the Internet. Some stories were more documentary-like, where filmmakers showed how recycling can be done in an authentic place.

In contrast to the subject-based stories discussed above, interdisciplinary stories are produced at the end of a series of lessons. While in subject-based stories the students used annotations to offer explanations, the students added subtitles to the theme-based stories on recycling in the postproduction phase. In both cases, they did so in order to pass the message to international peers online. In addition, some stories were performed in English.

Hanging Out

So far, digital stories have a close relationship with themes grounded in curricular requirements. In these cases, the teacher’s initiative is often primary. However, not all stories are based on teacher initiative to put forward a topic for student work. Some build on student initiative and aim to present a theme that projects, for example, instances of home life and culture or their hobbies. In this respect, digital storytelling relates to the formal content of learning both directly and indirectly and requires both aspects of engagement, as fun and as commitment to hard work, in order to produce meaningful outcomes. As these also

provide evidences of how these young people relate and hang out in their free time, they constitute an authentic way developing different types of competence and literacies.

In the following examples, the students put forward their own ideas and filmed digital stories aiming to introduce themselves to peers, present instances of their lives and culture, and tell stories about who they are and what their day-to-day life is like during school or after school hours. These are deviations from the original teacher plan for curriculum-based digital storytelling and are, therefore, student-driven in terms of themes and production mode. The products could be single- or multi-event stories but, in most cases, they focused on a series of events.

Telling the Story of Who We Are Stories that deal with self-presentations are descriptive with videos that use a static camera and mainly long shots. Self-presentations can serve as pedagogical icebreakers and are produced within the school timetable. Overall, the filmic practice seeks to give a picture of the class as a whole. However, in the *A few things about us* story, filmic practice shifts the focus of presentation away from the long shot class view to groups of students presenting themselves. This is the English version of introductions that students publish in order to address the international audience a month after posting the Greek version. This story not only shifts the focus of attention to the group level, but it also evidences how student digital skills have advanced as they can now put together a series of clips to come up with a remixed version of the story.

The *local museum* is an example of a story produced as part of flexible zone activities. Flexible activities in Greek primary schools are part of the school timetable but, unlike subject-matter-oriented teaching, are project-based and thus interdisciplinary in nature. As with the myths, thematic and filmic student choices allow for a longer, more complex narrative to take shape. The *museum* contrasts the fictional character of the *myths*. However, the students’ effort to construct a plot to hold the narrative together is evident.

Background music is used here to create a sense of reverence and respect for the past.

Telling Stories in After-School Hours The students tell stories about their hobbies during their free time. In one of these videos, a female student tells a story about riding and taking care of her horse. The story, filmed at a horse farm, documents the process of grooming, taking care of the horse, and a demonstration of riding equipment and offers some advice on how to keep the horse. Long shots alternate close-ups. Tracking shots following the horse transport the viewer into the scene and add to the truthfulness of the story.

The message seems to be clear: this is a story of young people who care about nature and non-human beings. In addition, as the students take care to make the subthemes of the main topic explicit, this story belongs to the multiple- rather than the single-event type. Similarly, in a digital story about computing and playing computer games, the main character (a male student) presents the kind of computer he has and gives tips to beginner and experienced gamers. The video includes both long shots of the student's room and close-ups of the computer. Clearly, technology is the subject here. The camera follows the human character, and at some point, close-ups reveal the internal part, the anatomy of the computer. At the end of the video, four male filmmakers apply the screenshot technique showing their faces to tell the audience who the video makers are. In this way, faces replace end titles.

Overall, the tighter to the curriculum the stories are, the less space is left for interpretive action. In subject-based stories, for example, the students test a chemical reaction. In terms of narrative theory (Kaplan 2003: 52–53), the students perform a configurative operation that mediates a preunderstanding and a postunderstanding of the chemical phenomenon. The narrative arc is narrow here, while the reality the students refer to is the textbook reality. A lot more co-text is thus needed for this event to offer something other than sticking to the formal interpretation of what knowledge is. In comparison, the configuration of action in interdisciplinary stories creates

possibilities for an array of new meanings from a diverse narrative arc. Within this framework, the notion of digital literacy becomes increasingly vague. A multidimensional approach to digital literacy aiming for communicative competence is therefore needed.

A Contemporary Metaphorical Definition of Digital Storytelling

Considering the above discussion and analysis, storytelling online with digital technologies can be overall seen as one expression of computer-mediated communication that opens up the space for nonunitary, nonfinite digital literacies and promotes reflective ways of using technologies as well as the context of use. Nonfinite digital literacies are dynamic, embedded in everyday life as social practice, and fit better with the current need to develop a critical understanding of digital media (Buckingham 2015; Engen et al. 2015; Lankshear and Knobel 2015). This view is linked with agency gained at the click of the mouse, while the computer and multimedia technology both manipulate and recreate reality (Murray 1997). Given the needs of the digital era, in order to be able to tell what is fake and what is true, it is not enough to be competent computer user. It is not enough for schools to educate competent computer users either. Users should be agentic, taught by agentic teachers aiming for communication. This view of agency in relation to a dynamic approach to digital literacy opens up the space for analytical modes of research for deeper understanding, a shift of perspective in pedagogy including structure and critical judgment, and a space for endless storytelling that the narrative perspective in education opens up.

Concluding, this paper draws from findings of empirical research, metaphor theory, and narrative theory in order to offer a holistic view of digital storytelling not only as a method where digital technologies are introduced into classrooms, but as a metaphor that has the potential to revitalize the sense descriptions of education in terms of how teaching is practiced, and research is designed and implemented.

Within this perspective, teaching supports interaction within formal and informal settings, aims for communicative purposes, and allows for agentic action for both teachers and students. In this way, on the one hand, teaching takes the form of professional action with singular, individual, and universal characteristics. On the other hand, learning becomes a process where students develop content knowledge and build identities as computer users and as language users. In order to match with these purposes, research should aim to explain and attain an in-depth understanding of the process and the participants and, therefore, should be looked at as both historical and empirical reality. In this way, researchers can gain a narrative understanding of the research by placing the focus on the whole as well as the parts of the study, and by embedding digital literacy as part of a wider communicative competence.

Introduction

Ever since the computer was contemplated as a learning device in the 1980s (Taylor 1980), adults have debated whether children’s access to technology in schools is essential or that the technology is merely a distraction from the real learning. It seems remarkable that almost 40 years after technology for learning purposes became viable, the significant use of these technologies can still be considered as peripheral. Even though children might use devices ubiquitously in their out-of-school lives, it is possible that they may still spend much of their school day reading handwritten text from a whiteboard, writing on paper with a pencil or pen, and using paper-based worksheets and notebooks. While they are probably using computers or mobile devices, this might be in limited ways: to “look up” information and to “type up” written work or for drill and practice, in the form of educational activities or games. This is an unacceptable scenario. The twenty-first century has been designated as “The Digital Age,” and the children of today will rely on digital technologies extensively throughout their lives. It is essential then that they learn to use digital tools effectively, understand how technologies work and can employ the technologies for their own purposes.

Fortunately, this realization has been growing over the last decade, and most school curriculums

now incorporate a component that relates to the use of computers, information technologies, and digital learning. For example, in the Australian curriculum, this is called digital technologies, and it has two strands: digital technologies knowledge and understanding and digital technologies processes and production skills (ACARA 2018). While this learning area typically encompasses a wide range of predicable content including knowing how computers work and using and working with data and the ethical implications of using technologies, a significant part of this curriculum is allocated to digital design. This focus requires learners to imagine digital solutions, engage with problem-solving cycles and computational thinking, design interfaces, manage projects to completion, and then implement their product. The new curriculum direction is certainly exciting and holds promise for learners to be empowered to truly engage with digital technologies, rather than simply functioning as a user, without any depth of understanding.

As this new approach to using technologies comes to fruition, there are a number of challenges that teachers face. In particular, the concept of “digital design” has widely been assumed to mean computer programming, and therefore, teachers are expected to teach “coding” to all children, even from an early age (Brewster 2015). This is demanding for teachers who do not consider themselves to be computer programmers, and perhaps this is restricted interpretation of digital design which is unnecessarily narrow.

While computer coding is a very important part of digital transformations, it certainly isn’t the only skill that will be required to advance digital technologies in the future (Scott 2015).

Learning to write code builds computational thinking, but this can also be developed through a range of activity where logic, persistence, and creativity are required. Further, a digital project needs much more than coding to be realized. It is important to recognize that a wide range of skills are required for digital development and society needs people with different expertise in order to work in teams to implement digital solutions. Rather than expecting every teacher to teach programming, a variety of digital design activities could be considered to address the key objectives

of the curriculum. This entry suggests that “digital storytelling” can offer an opportunity for children to engage in the intricacies of digital design while at the same time learning important digital technology skills and concepts.

Digital Storytelling

“Digital storytelling” is a process where the storyteller uses digital tools to create a media production about their life, the place where they belong or some other aspect that is important or relevant to them. The concept of digital storytelling is linked to the tradition of oral storytelling and it developed in the 1990s (Ohler 2013), when digital tools became available and affordable to the wider population. Educators quickly connected with this genre, and it has become a popular mechanism to engage children in learning.

An advantage of using digital storytelling for teaching and learning is that it develops new literacies. Lankshear and Knobel (2008) suggested the term “digital literacies” and identified that this category encompassed a wide range of skills, techniques, and approaches for using digital technologies to create and communicate. Sylvester and Greenidge (2009) found that digital storytelling could be used to support children who were struggling with traditional literacy and especially writing. Children were more motivated to create stories when they could communicate ideas with audio and image instead of relying solely on text.

During the process of crafting their story, these children had plenty of opportunity to revise their work, and consequently their stories became more sophisticated than if they had simply followed a traditional writing process. Digital storytelling also supports collaborative literacies where children can work together on a production (Nordmark and Milrad 2012). In this process, children learn the skills of media communication in a social way, through negotiation and reciprocal sense making.

Another feature of digital storytelling is that it gives individuals the permission to voice a story that is uniquely their own. The process is highly individualized, and therefore, it is essential that the storytellers are empowered to build their own

representation rather than being prescribed a formula for construction. This, however, doesn't mean that the teacher is redundant in the process. In fact, Ohler (2013) suggests that the opposite is more likely, with the student needing careful guidance and advice throughout the production. In this situation, the teacher uses scaffolding (Masters 2008) to work with the storyteller to provide just-in-time support, as the children plan and work through their project.

Digital storytelling provides a contextualized environment for children to apply digital tools. As they work through their project, they will identify features that will require digital solutions. They might need record video footage with a smart phone or a GoPro camera, use recording software to create a voice-over, or use animation software to blend drawn images with video footage. If they are using mobile devices, they might need to engage in "app smashing" (Kulowiec 2013) where they need to use a variety of apps in sequence in order to complete their digital resource. The applied context means that children learn how to use the app or device for authentic purposes.

The "messy" nature of digital storytelling provides an ideal environment to help children develop digital problem-solving skills. Although digital storytelling doesn't require children to write computer code, there are plenty of parallels. The children need to be able to imagine the end result and then use a top-down approach to break the problem into manageable parts. They then need to plan the design sequence and work through steps and decisions to reach their end goal. They will also need to consistently engage in problem-solving cycles where they identify their problem, look at options, decide on actions, and then evaluate the outcome: a classic "see, plan, do, check" model (Polya 1945).

Digital storytelling projects are sometimes seen as a "soft" option for teaching about digital design, but it actually is a complex process that engages learners at high levels for an extended period of time. This does not mean that we no longer need to teach computer programming in schools, but it does mean that teachers who incorporate this activity in their teaching program can meet many of the goals from digital technologies curriculum without needing to know computer programming. Further,

the skills acquired through this process will complement the ability to write computer code and will add a valuable dimension for students who wish to pursue a career in digital design.

Digital Storytelling in Action

The King Island Digital Stories (KIDS) project (Masters 2017) was designed to develop children's digital literacies and teach them about digital design through creating digital stories about their sense of place. The project was conducted with 21 children in a Year 4/5 class over a 10-week term. An ethnographic approach was used where two researchers worked with children in the classroom as active participant-observers (Johnson et al. 2006) to scaffold children to represent their story ideas. The children were told that their stories could be about any aspect of living on King Island and they should be in their own voice (first person).

The project was slow to start, but a weekly sharing session helped the children to conceptualize and develop their stories. As the resources began to emerge, it was evident that the children were engaging effectively with the process of digital storytelling, learning about digital design, and developing their digital literacies. The children each produced a short digital story in iMovie about their life on King Island and used a combination of still images, transitions, narration, video, green screen footage, animation, and/or music to create their resource. These stories were published on a website and were publicly available on the Internet. The stories were varied widely, but collectively communicated a picture of life on the island through the children's eyes.

The research found that, as a result of the project, the children's digital literacies developed considerably to include aspects such as image manipulation and audio production and concepts such as copyright and cyber safety. Further, the activity facilitated an authentic project-based design experience for the children, and this was sustained for an extended time period. There was also evidence that the children had embraced the genre of digital storytelling for their own purposes and were keen to create more digital stories after the project had concluded.

Digital Storytelling to Teach About Digital Design

All citizens of the digital age need a strong understanding of how digital technologies work and how they can be used to enhance their own lives and those of others. Many of the children in schools today will be employed in contributing to the technologies of the future, and their motivation and interest will be formed from foundations that are built when they are young. It is essential that teachers do more than simply use digital technologies in the classroom. Teachers have a responsibility to develop knowledge, understanding, and skills so that their students can confidently design and create digital solutions.

Code is the language used to create computer applications, and it has an important role in developing technological futures. However, this is a language that is completely foreign to many generalist teachers in schools, and as such, they lack the confidence to teach children how to write and apply it. As a consequence, many teachers either avoid implementing code-based projects in their classrooms or conduct “safe” programming activities, such as using task cards, so they can avoid the open-ended problem-solving required with digital design. The insistence that computer coding is taught across all levels in order to enact the digital technologies curriculum may be actually be impeding the capacity of teachers to lead meaningful digital design projects.

The Australian curriculum specifies that students need to be provided with “authentic learning challenges that foster curiosity, confidence, persistence, innovation, creativity, respect and cooperation” (ACARA 2018) in order to help them become “innovative creators of digital solutions.” It is possible that digital storytelling can provide a platform for teachers do this with more confidence. While teachers still need to scaffold learners through the process of development and cycles of problem-solving, the genre of storytelling is likely to be more familiar and comfortable for them. This familiarity will help them with their own skill development and therefore enable them to successfully lead their students’ endeavors.

Conclusion

Digital storytelling is a lovely way for children to learn about digital design. While it doesn’t involve hard-core programming, it offers plenty of opportunity for children to engage with real-world design skills, and it will certainly foster the traits specified by ACARA (2018). Further, digital storytelling provides a nice alternative for teachers who might struggle with the prospect of teaching programming. This will ensure that the classroom will become an environment where all learners, the teacher and the children, will be able to succeed in their digital design adventures.

Introduction

Acknowledgment of the ways in which becoming literate empowers children and adults to function at high levels in everyday life and participate in active social futures has been internationally recognized for a long time (New London Group 1996). With this in mind, it is apparent that young children enjoy using new (digital) technologies, yet many school-based learning contexts seem to be ambivalent about using them for literacy learning. For example, Flewitt et al. (2015) note that:

Children's immersion in digital communication occurs at a critical period in their lives when their emerging literacy skills (speaking, listening, reading and writing) and identities as effective and competent learners are being moulded by the conventions of the social and cultural worlds in which they live. (p. 291)

Accordingly, it becomes important to understand the ways in which learning ecologies can stimulate interest in becoming literate in our changing world, in contexts that incorporate the use of digital technologies.

The teaching of early literacy remains highly contested (Lynch and Redpath 2014). Internationally, reviews of the teaching of literacy/reading (e.g., in the United Kingdom, Layton and Miller 2004; the United States, Goodman 2011; Australia, NICHHD (National Reading Panel) 2000) have advocated centrally mandated standards-based curricula where “essential” knowledge and “basic” skills are stated and taught explicitly. The curriculum expectations are accompanied by an assessment and accountability testing regime that reinforce a traditional view of literacy based on encoding and decoding print texts (Lankshear and Knobel 2003). While there have been policy statements that endorse and promote the use of digital texts and experiences (e.g., DEECD 2006), the focus of early year's literacy curricula and classroom practices that are “print” based provides a stark contrast to our contemporary understandings of multiliteracies (Kalantzis and Cope 2012; Kress and Jewitt 2003; Lankshear and Knobel 2003) and the ways in which we know

young children can use new technologies (Marsh 2004; Plowman et al. 2010; Yelland 2007, 2017).

Thus, many classrooms still do not afford contexts and opportunities for young children in modern societies, to prepare for global social futures. Teachers receive contradictory messages about the value of new technologies for teaching and learning and often default to print literacy contexts in order to meet the standards required of them and the young children in their classes. In contrast, in out-of-school contexts, young children are excited by, and fluent with, digital texts and experiences (e.g., Marsh 2004; Rowan and Honan 2005). In this way, while definitions of literacy are changing, and the uses of digital technologies are increasing, the focus has remained on traditional literacy skills that “constrain and devalue student enactment and position literacy learning as a ‘struggle’ to encode and decode rather than a means of pleasurable self-expression” (Lynch and Redpath 2014, p. 150). Accordingly, heritage curricula are regarded as being inadequate to empower and prepare students for lives in the twenty-first century and are even at odds with their home experiences (Marsh 2004; Yelland 2007).

Becoming Literate in the Twenty-First Century

There would seem to be general agreement that being literate is a fundamental skill in order to be able to fully participate in society and forms the basis for lifelong learning (UNESCO 2016). However, what “counts” as being literate has changed over time. A broad definition of literacy (UNESCO 2004, p. 13) has wide acceptance and encapsulates skills, cultures, and contexts:

Literacy is the ability to identify, understand, interpret, create, communicate and compute, using printed and written materials associated with varying contexts. Literacy involves a continuum of learning in enabling individuals to achieve their goals, to develop their knowledge and potential, and to participate fully in their community and wider society.

Becoming literate in the varied contexts of oral, written, printed, and digital media is essential to being able to function effectively in contemporary societies, and this process is enabled by using the “21st century skills” (Trilling and Fadel 2009) of creativity, critical thinking, collaboration, and communication. Research has challenged conventional print-based definitions of literacy, and a variety of studies have illustrated the ways in which digital technologies make an important contribution to early literacy competencies (Flewitt et al. 2015; McKee and Heydon 2015; Plowman et al. 2010; Yelland and Gilbert 2013, 2014).

Additionally, the foundational skills and concepts required to become literate and numerate are an integral part of being a new learner in the twenty-first century. We consider literacy and numeracy together here because it is almost impossible to separate them, and we believe they establish the foundation for all subsequent learning. This process begins at birth and occurs across both formal and informal contexts of learning. Fluency in literacy and numeracy *enables* the 21st century skills and supports *growing a generation of new learners* who are able to fully participate in society. It is essential that a range of pedagogies (teaching strategies) be used so that children can both acquire the foundational skills and apply them appropriately and creatively in relevant contexts that constitute their lifeworlds.

Multimodal Learning, iPads, and Learning in the Early Years

It is contended that one of the significant differences about learning in the twenty-first century is that it is *multimodal* (Jewitt 2003; Kress and Jewitt 2003; Yelland 2007, 2015). Young children experience learning in a wide variety of contexts and learn with different resources that are found both in their “real” worlds and via new technologies. *New learning* (Kalantzis and Cope 2012) requires teaching strategies and opportunities for learning to meet the needs of communities of learners who are experiencing changing social

futures. New learners are responsive to change and dynamic in their thinking so that they are able to adjust to changing times effectively. They are enacted from a sound knowledge base of *foundational* skills that enable ideas to be generated and tested. They are encouraged by learning experiences characterized by engagement with new ideas, inquiry, exploration, curiosity, and a passion for learning. They exist in communities of learners who have a strong sense of social justice and empathy so that being a good citizen is an integral part of the moral imperative of their education.

In planning for these imperatives, it is essential, in the twenty-first century, that all children have access to new technologies and that they are able to use them, when appropriate, to learn. New technologies incorporate the range of devices (hardware) that are available in the marketplace. They are ubiquitous and constantly changing and include computers, tablets, smartphones, and a myriad of other mobile devices. For the past 5 years, there has been an increasing surge of interest in the iPad for learning (e.g., Flewitt et al. 2015; Lynch and Redpath 2014; Rowe and Miller 2016). Their touch pad technology, and mobility, meant that they could be used easily and widely. Many research projects have explored the viability of the new technology and presented exemplary studies based on empirical observation data (e.g., Agostino et al. 2016; Lynch and Redpath 2014; Rowe and Miller 2016; Yelland and Gilbert 2014, 2016). The research that has literacy as a focus (e.g., Flewitt et al. 2015) has generally shown that, with pedagogical support, teachers are keen to incorporate tablet technologies (iPads) into their early literacy experiences. Additionally, using iPads has provided increased and quality learning experiences that enable collaborations, communication, and independent learning. For example, McKee and Heydon (2015) conducted a fascinating exploratory study with kindergarten children and senior citizens, investigating the opportunities for print literacy to function in multimodal assemblages. Their findings provide evidence of deep learning via engagement with ideas and people and opportunities to refine their print literacy capabilities in

the context of multimodal ensembles. Further, Rowe and Miller (2016) explored the potential of iPads for bilingual preschool children to create eBooks over a period of 2 years. Their work illustrated the potential for multimodal representations to enhance literacy in both languages that were not possible without the technology. Agostino et al. (2016) worked with struggling readers and a particular letter-focused application (app) called *LetterWorks*. This study illustrated that there is a need to incorporate the use of iPads, or other technologies, into literacy activities as a whole and not view them as isolated learning opportunities. Further, they stressed the need for teachers' philosophical stances to be aligned with using new technologies for learning.

From the studies available, it becomes apparent that the apps available can be considered in many ways or categories, but at a practical level, to consider them on a continuum from entry level to advanced is useful. *Entry-level* apps can be basically designed for entertainment, but they can also provide contexts for being introduced to the foundational skills of literacy and numeracy (e.g., introducing letters and numerals and simple words) in a stimulating way. *Advanced* applications stimulate creativity, critical thinking, collaborations, and the sharing of ideas and are only possible in environments that encourage diversity and personalized learning. The difference has been characterized in terms of being a *consumer* or *creator* with the support of new technologies (Yelland 2007). The latter role resonates with new learning, providing experiences required to excel in contemporary times. But, in fact, children are unable to engage with the higher levels of learning required in the advanced apps, unless they are fluent in the fundamental skills. As such, learners should be supported to participate in a range of activities from simple to more complex. Hence, the type of applications becomes of major importance.

Young Indigenous Learners

The issue of young Indigenous children experiencing problems attaining the benchmark levels

of attainment in literacy and numeracy has been identified as being a problem for over a decade (Frigo et al. 2004). This is not unique to Australia, as Hare (2011) has noted. The same trends are evident both in Canada and New Zealand. Hare (2011) also stated that in order to attempt to address the issue, the “challenge for educators who work with Indigenous children. . . is to create a space for Indigenous knowledge. . .” (p. 408). This needs to begin in the early years since research has indicated that it is overwhelmingly evident that the early literacy ability is a strong indicator of later success in school (e.g., Roberts et al. 2005; Senechal et al. 2006). The “funds of knowledge” framework (Moll et al. 1992) informs us about the importance of valuing and incorporating family knowledge as part of any early literacy program. While it is widely recognized that we live in a multicultural society (and in Australia, where this topic will be considered in depth, this is increasingly important), it is also evident that there is minimal research about how we might enact this in schools with Indigenous students to address the significant difference in achievement. Hare (2011, p. 391) has in fact suggested “Developing an awareness and appreciation for Indigenous approaches to living and learning will provide the basis for improving the home-school connections that being with early childhood for Indigenous families.”

Indigenous ways of knowing and being have their origins in an oral tradition of storytelling that has continued into modern communities (Burnett 2015). Additionally, we know that maintaining cultural relevance and providing local experiences to locate knowledge building are a fundamental aspect of learning for young Indigenous children (Brady et al. 2003; Nakata 2003). Nakata (2003, p. 12) advocates a “ground-up” approach and contends that this has to take place with the realization that the “forms of literacies that are required to understand the world are constantly changing.”

Burnett (2015, p. 44) highlighted that at the core of Indigenous knowledge is its “imaginative and pictorial character.” He advocated creating contexts for learning where oral storytelling is encouraged so that children can become aware

of the impact of spoken language. Nakata (2010) extends this idea by recognizing that this tradition can incorporate “writing” in order for the children to build a repertoire of literacy practices so that they are able to function more effectively in contemporary society. Hare (2011) maintained that this was possible since Indigenous ways of knowing resonate with emergent theories of multi-literacies and multimodality. She advocated that pedagogical approaches that were culturally specific were needed in order to support emergent literacy learning for Indigenous children. These included sharing stories based on personal experiences that can arise out of increased awareness and interactions with families in communities. These enhanced collaborations can then be documented with the use of digital technologies (Yelland 2007; Yelland and Gilbert 2014) in multimodal formats. The benefits are enormous since, as Hare (2015) noted, when the use of Indigenous narratives is incorporated into learning experiences, literacy skills (e.g., story knowledge) result in increasing vocabulary and comprehension, which are essential foundational skills for early literacy.

Digital Empowerment: Emerging Digital Literacies

The remainder of this section discusses the potential of iPad technology to enhance emerging literacy practices for preschool Indigenous children in Australia through a case study. Indigenous children have been found to be performing less well than their nonindigenous counterparts in national literacy tests at primary and secondary school levels. This study involved working with teachers and children in four Indigenous preschools in order to investigate how to support their literacy and numeracy learning using iPads. The design included a plan to build on Indigenous oral literacy traditions that would enable the children to acquire the foundational skills to support and empower them to become fluent in extending their abilities to read and write in varied modalities. This rested on the belief that all children need foundational skills in literacy and that the early

years were vital focal points for learning. The foundational literacy skills included being able to recognize letters, sounds, some everyday words, knowing and using numbers, recognizing shapes and objects, and being able to articulate events and everyday practices that occur in conversations. In this project opportunities for the children to consolidate their foundational skills with iPad apps were planned linked to the preschoolers' everyday experiences and their specific cultural context. These experiences formed the basis of creating multimodal texts so that the children could read and continue to build their vocabulary as well as provide contexts for engaging with literacy, based in their own lifeworlds.

These experiences then formed the basis to build on Indigenous children's funds of knowledge (Moll et al. 1992), such as their oral literacy tradition, to create contexts for them to become literate as a fundamental right to living in the twenty-first century. It has become evident that in order to be "ready" for school and to participate in life after school, the foundational skills of literacy (and numeracy) are essential in order to access services and to contribute to communities in a variety of ways. Indeed, in the early years of school, being able to communicate ideas and represent your understandings effectively involves using these foundational skills on a daily basis. Such emergent skills can be encouraged and supported in quality early learning environments.

In Australia, like many countries globally, performance in literacy (and numeracy) is measured by national testing. In Australia, it is called the National Assessment Program Literacy and Numeracy (NAPLAN). NAPLAN was designed in order to "test the sorts of skills that the government believe are essential for every child to progress through school and life" (ACARA 2013, p. 67). There is an explicit recognition by the ACARA that being fluent in literacy and numeracy is foundational to later success in life and that the items in NAPLAN reflect the attainment of those skills. The most recent data (ACARA 2015) about test performances, which are conducted in Years 3 (8–9 years), 5 (10–11 years), 7 (12–13 years), and 9 (14–15 years), indicated that 18% of Indigenous students failed to reach the

minimum standard for reading and writing (6% for nonindigenous students). Sixty-one percent of Indigenous students were below the benchmark for spelling, grammar, and punctuation, while 78.7% were above the minimum standard for literacy in Year 3 (95.6% for nonindigenous).

In 2008, the Council of Australian Governments (COAG – Closing the Gap on Indigenous Disadvantage. https://www.coag.gov.au/closing_the_gap_in_indigenous_disadvantage) agreed to six targets that sought to address the disadvantages faced by Indigenous Australians. These goals pertained to life expectancy, child mortality, education, and employment. Two of the goals directly relate to research of a project reported here. They were to:

- Ensure access to early childhood education for all Indigenous 4-year-olds
- Halve the gap in reading, writing, and numeracy achievements for all school-aged Indigenous children by 2018

The project, known as *Closing the Gap*, had broad goals to support Indigenous health, welfare, and education and planned to encourage early childhood development as well as significant investments in schooling. The National Partnership Agreement on Indigenous Early Childhood Development was designed to provide early learning and support for Indigenous families and stated targets for improved health for both mothers and their children. One of its major aims was to improve Indigenous families' use of early childhood development services to optimize the development of the children, and an overarching goal was that Indigenous children should acquire the basic skills for life and learning. Another goal was to "prepare children for school" (p. 30) with growth in literacy and numeracy attainment being viewed as an essential part of this process. One of the findings from the final report (Final report on Indigenous early childhood development. <https://www.coag.gov.au/sites/default/files/Report%20-%20Evaluation%20of%20the%20National%20Partnership%20Agreement%20on%20Indigenous%20Early%20Childhood%20Development.pdf>) indicated that there was anecdotal evidence

that early learning activities in the child and family centers were leading to children being better prepared for school. Implicit in the plans and the actions taken as part of the project was a recognition that investment in the early years pays “significant dividends later in life” and that the investments “are making a positive difference” to the lives of Aboriginal and Torres Strait Islander children, families, and communities. There was a recognition that evidence-based practice was needed to support the sharing of exemplary educational practices since these had the potential to transform the lives of Indigenous children as they progressed through schooling systems to achieve more favorable outcomes.

Indigenous Literacies

This project was based on the contention that in order to encourage and facilitate new learning in the twenty-first century, Indigenous learners need access to new technologies and to be provided with opportunities to master the fundamental skills of literacy and numeracy and opportunities to apply them in culturally relevant ways so that their experiences are meaningful and learning outcomes improved. This will then provide the context for decision-making about life choices, such as employment and participation in society. Thus, there is an imperative to *grow a generation of new learners*, and this begins in the early childhood years.

The study was grounded in sociocultural theories of learning (Vygotsky 1978) in which children learn in a social context before internalizing any new information. This approach resonates with taking an Indigenous perspective to knowledge building that is culturally based in the oral tradition of storytelling as well as linking to the notion of social futures inherent to pedagogies of multi-literacies (New London Group 1996) and multimodality (Kress and Jewitt 2003).

The Context of the Study

The study was designed to explore and document pedagogical contexts for using tablet technologies

(iPads) in early learning scenarios (4-year-old kindergarten groups). Four centers participated in the project. They were part of the Multifunctional Aboriginal Children's Services (MACS) system, located in the capital city of the state and in three regional centers.

The study was designed in order to consider the potential for *new learning* (Kalantzis and Cope 2012) with *new technologies* and support teachers to use tablets to transform their pedagogies and practices in early childhood Indigenous education. There was a stated need for evidence-based practice to support culturally appropriate ways of becoming literate and numerate. The aim of this project was to document and share what might work, since we believed these had the potential to transform the lives of Indigenous children in other locations.

Previous research (e.g., Yelland and Gilbert 2013, 2014, 2016) had shown the variety of ways in which tablet technologies could benefit learning in preschools. This project sought to extend this work with Indigenous educators and children to encourage new learning that was culturally relevant and would enable the children to acquire fundamental skills in literacy and numeracy that they could apply in diverse contexts. The researchers participated by observing and interacting with the children, caregivers, and teachers, in a participant observation methodology. Participant observation can be defined as a method in which “the researcher is taking part, to some degree, in the activities of the people being observed” (Deacon et al. 1999, p. 251). The aim of participant observation is to gain access to everyday practices, which are difficult to describe or reproduce in group discussion or interview (Mikos cited in Struppert et al. 2010). Through participation in the context, the researcher can achieve a better understanding of the practice, roles, and cultural patterns of the participants (Mikos cited in Struppert et al. 2010). Visits were made to the MACS on a regular basis. For the MACS located in the city, this was 1 day a week for 6 weeks in terms 2 and 3. For the rural centers, the visits occurred on two occasions for 2 days in length, during the same terms.

There were three sources of data in the project. First, daily reflective notes reflected the events of the day recalled as a narrative. These included descriptions of the children using the apps as well as conversations with the children as they embarked on various play-based experiences. Second, the educators in the three centers shared their planning documents and observations by making them available to the research team as well as in conversations with them during the visits. All of the educators were interviewed in their centers, prior to the start of the participant observation period. This was in a semi-structured interview schedule which included questions about how they viewed the role of technologies in the lives of young children, the advantages and any disadvantages of using them, the types of apps they thought were the most useful for their program and why, and what were the differences in learning that they perceived were happening from using the iPads. In analyzing the data, themes were derived to describe the children's interactions in the learning environments in the ethnographies and then linked with the data derived from the interviews with the educators and with their planning documentation to explore the ways in which using the iPads was connected to their beliefs as well as their design of learning experiences.

A total of 10 educators and 63 Indigenous children participated in the study. The average age of the children was 4 years and 3 months with a range from 3 years and 7 months to 5 years and 5 months. The educators were experienced, with each one having taught preschool children for over 5 years. Seven of the educators were Indigenous and three nonindigenous.

The Apps

Apps were chosen in consultation with the educators. They were trialled prior to the commencement of the project to determine their usefulness prior to purchase. There were many more entry-level apps than open-ended creative ones. The apps were introduced to the children as they showed interest in using them. The advanced

apps were introduced by the researchers, and the children were invited to participate and play with them if they wanted to. There was a planned visit to the local cultural center, and an Indigenous Children's Day occurred while the research was in progress. Both of these events provided a context for creating an electronic book while the study was in progress.

The entry-level apps enabled young children to start recognizing each letter and lead to reading words and creating their own stories. There are a great many of them available on the market. For example, in *Alpha Tots*, each letter of the alphabet is introduced individually by name, and then a word beginning with that letter is accompanied by a graphic so that the child can see how the letter is used in context. This is done for both objects (e.g., book, car, house) and actions (e.g., mix, fix). In *iWrite*, children are able to use their fingers to trace over the letter or numeral and feel how it is shaped in a very tactile experience.

Entry-level apps were used to support the acquisition of fundamental skills in literacy and numeracy. In literacy, this meant recognizing letters and the corresponding sounds and sound blends and building a strong vocabulary of everyday names and activity words. For numeracy, it included:

- The ability to recognize and use early mathematical *language* such as positional and relational terms (e.g., up, down, over, under, in, out), using, for example, *Bugs and Buttons* and *Bugs and Numbers*
- The *names* of colors and shapes, using, for example, *PB Shapes and Colors*
- *Using* the basic processes of describing attributes, matching, sorting, classifying, and making and using patterns, using, for example, *Bugs and Buttons*
- *Recognizing and using* numerals to create groups of specific numbers of items and combining or reducing them as an early introduction to addition and subtraction in context, using, for example, *iWrite numbers and letters*, *Alpha Tots*, and *Monkey Preschool Lunchbox*

Many early reading books and resource materials do not contain representations of Indigenous

children. In this project, advanced apps (*Book Creator*) were used to create eBooks that included the children themselves in the storyline. Aspects of the children's daily lives were included so that they could apply their learning and be involved directly in making and interpreting the eBooks. The study included learning contexts in which the children were challenged to explain their experiences using (oral and written) language. The camera in the iPad meant that everyday play activities could be photographed, or videoed, and saved for later conversations about aspects of the play scenarios. For example, if the children built a construction with blocks, subsequent discussions about the relative sizes of the blocks, their position in the structure, and how many blocks were used could occur. Similar discussions could be had about a painting or a collage or in relation to any of the indoor or outdoor activities planned by educators.

The Educators

The data from the semi-structured interviews revealed that the educators ranged in their own levels of confidence with new technologies and their feelings about using them. However, they all indicated that they were "excited" and ready to "embrace" the iPads and ready to learn new ideas that they could try out with the children in their kindergarten, which were preschool centers with children (aged 4 years) in the pre-compulsory years of education.

They all indicated that the *Early Years Learning Framework* (EYLF) (Department of Education, Employment and Workplace Relations 2009) was an important policy imperative that guided their work. The EYLF provided the context for early learning and the reporting framework for all early childhood educators in Australia. It was designed to support learning contexts in which all young Australians become:

- Successful learners
- Confident and creative individuals
- Active and informed citizens

The framework characterized children's lives in terms of them *belonging*, *being*, and *becoming*, and it had five learning outcomes that were inter-related and supported deep learning (defined below) via careful planning of experiences. They provided the contexts for children to:

- Have a strong sense of identity
- Be connected with and contribute to their world
- Have a strong sense of well-being
- Be confident and involved learners
- Be effective communicators

Fullan and Langworthy (2014) contextualize deep learning by describing it as being based in new pedagogies focused around creating learning partnerships between, and among, teachers and students. The dynamics of the new relationships mean that the students are more engaged and have more autonomy over designing their learning experiences. Their learning scenarios are based in authentic experiences enabled by new technologies and usually designed by the students themselves as investigations. In this way, deep learning opportunities are created.

The EYLF suggests that information and communication technologies (ICT) can be beneficial for planning learning opportunities in the early years. There is recognition that ICT can support collaborative explorations and investigations and that they constitute a medium for expressing and communicating ideas. However, in reporting for accreditation purposes, examples need to be provided in the form of observations of children engaging in learning.

In the conversation with the educators, it was evident that they felt a primary goal for kindergarten which was to have the children "school ready" by the end of the year. They indicated that this, in part, included that at the end of the kindergarten year, the children would be able to recognize the names and sounds of letters of the alphabet and numbers up to 10. Yet they recognized the value of social aspects of learning, such as collaborating with others and being able to be engaged in an activity for a sustained period of time. Each one of them thought there was an imperative to have

technology, such as iPads, in their kindergarten room. They made statements to indicate that they felt that using technology was essential for living and learning in the twenty-first century, particularly for Koori (Indigenous) children as many did not have them in their homes. So, the educators thought that coming to kindergarten and having both structured and unstructured learning experiences with the iPads were important for the children's early learning. They viewed the advantages of using iPads as being related to engagement with learning, improving fine motor skills, having opportunities for new and challenging experiences, preparing children for the "real" world, and enabling them to find out new information. They viewed the disadvantages in terms of being able to manage the time around the use of the iPads and of sharing them between the children in the groups when so many wanted to use them. This was also related to concerns that the children would become too reliant on them in their play and that they would want to use the iPads exclusively and not play with traditional play materials. They also expressed a concern about safety issues online.

Emerging Literacy Skills

Observations revealed that the entry-level apps afforded opportunities for the children to acquire the foundational skills of literacy and numeracy. The experiences with the entry-level apps represented a focused time on particular skills and concepts that the educators could build on in their conversations with the children while they were playing with them, as well as in other learning activities. They could also help the children to make connections about the concept with the different activities that were provided as part of the planned program in the kindergarten.

For example, with the app *Alpha Tots*, it was observed that the children made connections between the various letters of the alphabet and the letters that make up their own names as well as familiar items (table, chair, and carpet) around them (Fig. 1). The audio features of these apps also helped those children who experienced

problems with the pronunciation of words. The apps encouraged children to recognize letters and words and to say them out aloud. For example, when the letter "c" was introduced, it was accompanied with the name of the letter and the hard "c" sound. The action of cutting was introduced with the cutting of the strings on some balloons. In response, one child, Brian, immediately said "balloons" start with a "b".

In interactions with the children, it was noted that once the letters were recognized, they could be combined to make words, so that in an app like *Monkey Preschool Lunchbox*, various words could be read aloud. The educators were encouraged to talk with the children both individually and in small groups and ask them questions such as:

- What letter is this? What sound(s) does it make? (Strawberry starts with "S.")
- Can we think of a word that starts with this letter? What about another word? (Sally starts with an "S" and Sand starts with "S.")
- Can we think of a word that has this letter at the end? (Cars end with an "s.")
- This fruit is yellow. What other things can you see that are yellow?

These conversations became an integral part of the learning process.

By using apps such as *Alpha Tots* and *Monkey Preschool Lunchbox* with their visual, audio, and

Digital Technologies and Literacy Contexts for Young Indigenous Children, Fig. 1 Alpha Tots

linguistic learning experiences, conversations about letters, sounds, and words with the educators proved to be very worthwhile. With apps such as *iWrite*, the children could trace over letters and numerals, and the experiences became tactile. This enabled them to become familiar with the structure of letters and numerals and how they felt. In doing these activities, the children were guided by the app in a structured way, in terms of the direction of each stroke, and were then able to transfer this experience to paper and pencil representations of the letters and numerals. At the same time, the children were extending their personal vocabulary of words and numbers, which they could then apply to other learning activities.

Playing with apps like these, and talking with their educators, enabled the children to experience early literacy concepts in dynamic interactive contexts that built on and extended their “real-world” play experiences. Taken together, these multi-modal learning opportunities prepared the children to experience reading with both electronic and traditional reading books.

During this phase of the research, eBook stories were read with the children such as *Teddy's Day* and *Peppa Pig at the Fair* in order to build on the foundational skills. These eBooks extended traditional reading experiences in a variety of ways. First, the eBooks had “read along” modes. A child could choose just to listen to the story in tandem with the pictures. Second, the story could be retold using their own words.

Each book contained a series of activities on each page that extended the scope of the book. For example, on one page in *Teddy's Day*, children could create a drawing, which then went on to the wall of the living room in which the character is playing with her Teddy on that particular page (Fig. 2). Alternatively, they could make a jigsaw with the characters as they were playing. With the *Peppa Pig* book, they could choose to modify the text by recording their own words for any page. The pages of the eBooks were full of items and actions that acted as a catalyst for language and conversations about a wide variety of things that children found interesting, which might be about dancing (there were dancing mice in *Teddy's Day*) or eating fairy floss at a special event (*Peppa Pig*).

Having opportunities to use the foundational skills, concepts, and language was not just experienced with iPad apps. Using the tablets formed part of the daily program and was linked with other play materials located both inside and outside the classrooms. In the study, it was found that the experiences with the apps on the iPad acted as a catalyst for more focused conversations when the children were playing in other areas of the center. On one occasion, after playing with *PB Shapes*, Marlowe (pseudonym) was playing in the outside area, and he called to Lara (educator pseudonym) and said “Look Lara, there are shapes out here like in the game. I can see a square and a circle and a rectangle over there!”

Digital Technologies and Literacy Contexts for Young Indigenous Children, Fig. 2 eBook: Teddy's day drawing on the wall

Scenarios such as this happened both spontaneously and with scaffolding from the educators. All the educators were familiar with basic mathematical language, concepts, and beginning skills from a professional learning experience around *Early Mathematical Explorations* (Yelland and Gilbert 2014) that happened in the year prior to this project. This project took an integrated and practical approach to language and conceptual learning from birth and provided educators with strategies to support early learning for literacy and numeracy.

It is recognized that once children have acquired foundational skills, they are able to communicate and make meaning in more effective and sophisticated ways. In this project, the children were to *apply* their knowledge and skills in new and diverse ways and were able to use the iPads to do this as well as in other play-based activities.

This Is Me! An Introduction to MadPad

When children are able to engage in conversation with others, they can embark on different levels of meaning-making in which they can describe and create new narratives. *MadPad* is an app that enables a montage of 12 pictures and sounds to be created and replayed (Fig. 3). One of the things

that was found useful when introducing a new creative app such as *MadPad* to young children was to show them an example. They could then use this to help produce their own version or innovate on it because they could see some relevance of it to their own experiences and interests. In this instance, *MadPad* enables users to view and play with other users' *MadPad* creations on the Internet and share on *YouTube*. In one, a series of 12 photographs and sounds of a car were arranged in a 4×3 matrix, and in others, there were various scenes and sounds from daily lives as well as others using a range of musical instruments. The idea is that the clips are short (10 seconds) and "snappy" and can be played individually or collectively. It is the range of sequencing the items and innovating on the sounds that makes it fun and lifts its creative potential so that each time it is a different experience.

For the young children in the centers, the *MadPad* montages provided the context for a short burst of conversation or sound creation that could then be linked with others to form a whole matrix of sounds. These then acted as a catalyst for exploring the sounds or ideas encapsulated in the matrix of videos. When working with preschoolers, it was found that several "takes" with each child were needed before they could use the

**Digital Technologies and
Literacy Contexts for
Young Indigenous
Children, Fig. 3** MadPad

10-second recording. At the most simple level, MadPad montages in which the children introduced themselves and said what they liked best were developed. For example, “My name is Mira and I like cows!” Other completed montages included a collection of playground sounds, favorite spots in the garden, and a statement about favorite animals. All of the MadPad montages were played with repeatedly by the children and led to a rich source of conversations.

Creating Scripts with Play School and Sock Puppets

Two other creative apps were useful to encourage talk and build vocabularies. *Play School Art Maker* lets children create various scenarios with their favorite characters from the popular television show. The children can choose a setting (e.g., a farm, the beach, underwater, bedroom, or the moon), place the characters and appropriate items in the scene, and then record a 1-minute video in which they can add their storyline with their voice. The videos can be compiled and made into an eBook or simply be saved in the app for later viewing. The scenes created provide very useful catalysts for talking about the various forms of mathematical language. They can stimulate conversations around positional and relational terms and incorporate activities such as counting and finding patterns in the scenes that have been created. The children loved to playback their creations and share them with their friends. In the process, they talked about the various characters and items in each scene as if they were friends. Each video constituted a multimodal language experience that was created by the children themselves.

In *Sock Puppets*, a background and characters can again be chosen and incorporated into play-based scenarios. They range from endearing “Sesame Street”-type characters to ghosts and aliens. Backgrounds and props can be selected before a play is created. When the children began playing with *Sock Puppets*, they often just uttered “gibberish” and made sounds, but as they became more familiar with the genre, they created short

interactions in which they played both parts of the puppets they were creating. For example, Susi chose two Muppet-like puppets – a (pink) girl with yellow hair and a pink “animal” puppet. She placed them in a “country” scene background and then created her script spontaneously:

S: (with puppet 1 (P1) the girl) We are in the bush Spotty

S: (with animal puppet (P2) highlighted) I like it here. It's sunny

S: (P1) Run after the ball Spotty

S: (P2) I can catch it!

The children seemed to enjoy these activities and carefully thought about the words that they might use when they were recording their short play sequences. They encouraged the children's talk and, after the initial play sessions where they first found it difficult to figure out which puppet they had to speak for, became adept at creating short scenes like the one above.

Advanced Apps: Making eBooks with Book Creator

By far the most advanced and exceptional use of the iPad was in the creation of eBooks with an app called *Book Creator*. These eBooks could also be saved as *iBooks* in a different app. Kindergarten-aged children (4 years old) are in the process of acquiring literacy skills that enable them to explore the world and share their ideas with others. They need to practice their skills in a rich variety of contexts. This may include playing at shopping and using the appropriate terminology; using items and engaging in conversations; talking about constructions while playing with blocks; and creating eBooks on the iPad.

The availability of children's books that include Indigenous children as characters is limited. It is possible to explain to educators how to build their own books, and after a few examples, they are able to create their own. The books made in this project included the children in the centers, and their everyday experiences were the source for the stories in each of the texts. These included:

- An Indigenous children's celebration day: on this day the center arranged for a range of activities including both modern and traditional Aboriginal dancing groups.
- A visit to the local Indigenous cultural center (see Fig. 4).
- Making a book about aliens, which seems to be a constant source of curiosity to children from every culture.
- Exploring the garden created at the center.
- Playing in the playground (see Fig. 5).
- Finding out more information about our group of friends.

The eBooks were multimodal. They included text, drawings, photographs, and videos. The text was both written as well as being spoken by the children. When the books were finished, the children could share them between the two iPads in each center via *AirDrop*, and then they could be read whenever any child chose to do so. This was quite frequent, as the books seemed to take preference over traditional books. The eBooks provided a context to practice reading and for listening to stories. The narratives had direct and personal relevance to the young children's lives. The children wanted to sit and read the books that they had made themselves. This, in turn, had the effect of increasing their vocabulary and improving their reading capacity.

The use of the iPads to make eBooks documented the activities that the children participated in. They illustrated examples of using literacy and numeracy in meaningful ways. For example, at a local cultural center during one session, the eBook became a dynamic and permanent record of the day's events that could be revisited at any point in time when individual or groups of children wished to recall them. In this particular example, the visit to the cultural center included hands-on experiences with traditional artifacts as well as listening to Uncle playing the didgeridoo and the children guessing which animals he was mimicking on the "didge." Uncle could not be present back in the center, so the book became a permanent recollection of his playing and the children loved to recall this in their later reading of the book.

Some centers also decided to print the books as well as have them in the electronic format. This provided the context for another dimension of multimodal representations of the books and conversations around why the video could not work in the printed version – a feature that was important for many of the children in the various groups. A benefit of printing the eBooks was that they were able to use QR (quick response) codes. QR codes were created using an app called *QR Code Generator*. For example, an eBook was made about a scooter race held at a kindergarten one

Digital Technologies and Literacy Contexts for Young Indigenous Children,

Fig. 4 Bangerang painting

Digital Technologies and Literacy Contexts for Young Indigenous Children, Fig. 5 In the playground

Digital Technologies and Literacy Contexts for Young Indigenous Children, Fig. 6 QR codes: Scooter race

morning. The eBook contained videos of each child racing around a track in the playground on the scooter. These videos showed how long each child took to complete a circuit. The aim was to find out who was the faster on the scooter in the group. Each of the videos was then uploaded to a private *YouTube* account, using the *YouTube* app on the iPad, and assigned a URL. The URLs were uploaded individually into the *QR Code Generator* app, and a unique QR code was automatically created for each video. The unique QR codes were printed and pasted onto each respective page of the hard copy. The children could then use their iPads to scan each code to view their video.

In another example of using QR codes, a poster of the children’s favorite things was created. This included a photograph of each child in the group with a QR code placed next to the image. When scanned, the QR code linked directly to the video on *YouTube* of each child speaking about what they liked doing best (Fig. 6).

Conclusions

This entry has provided empirical examples of the ways in which iPad use, with a range of exemplary apps, has the potential to enhance, and extend,

new learning opportunities for Indigenous children as young as 4 years of age. In doing so, it provides contexts for them to become literate as these activities are embedded in play-based early childhood programs. The observational data have shown that this can be achieved in four specific ways. Firstly, they can support the acquisition of early foundational skills in literacy (and numeracy). There are a myriad of apps that claim to teach “basic” concepts. A small number can be used in explicit teaching moments while children are engaged in both outdoor and indoor play activities. The use of these “entry” apps in the case study’s playful context introduced, encouraged, and reinforced the application of these fundamental ideas and connected them to other learning activities in the centers. Secondly, it was not just being exposed to the apps that made them valuable learning resources. Teachers used specific pedagogical strategies to scaffold the children’s learning. They asked questions of the children while they were playing and encouraged them to articulate their responses orally. They modeled the use of the words and sentences in various activities and were able to encourage the use of skills and particular concepts that were complex and could stimulate multimodal thinking in a range of experiences. Thirdly, the iPads provided a medium in which the children’s everyday activities and participation in special events could be recorded and revisited. For example, in the project the *Book Creator* app was used to create eBooks that were constantly revisited by the children to recall what they had been doing at the center at that particular point in time. Finally, all the activities provided contexts for using language and communicating with other children and with adults. They became important focal points of conversation and constituted opportunities to use language in a variety of modalities. It was found that engaging in the iPad activities stimulated conversations between the children and that the educators were also able to engage the young children in interesting and sustained talking to build their early vocabulary and skills in reciprocal talking.

The data from the case study adds to the corpus of research literature discussed at the beginning of

this article that consider the ways in which digital technologies impact on the emergent literacy skills of young children. Rethinking twenty-first-century literacy to go beyond the print literacy imperatives to incorporate digital literacy opportunities is a major concern for research and practice. Recent studies (e.g., Flewitt et al. 2015; Lynch and Redpath 2014; McKee and Heydon 2015) have supported claims arising from practices that seek to do this, providing empirical examples of the ways in which this might be achieved.

Introduction

This entry explores the use of digital technologies in higher education. There is now widespread recognition that in the twenty-first century digital technologies, particularly portable hand-held devices capable of Internet connection, present opportunities and challenges to the way in which student learning is organized in schools, colleges, and institutions of higher education. Traxler (2010) suggests such devices are pervasive and ubiquitous, conspicuous and unobtrusive, noteworthy and taken-for-granted with everyone typically owning one, using one and often having more than one. Consequently, it has been argued that the availability of such devices, controlled mainly by the student and not the teacher, has the potential to change the traditional dynamics and pedagogical patterns of the learning environment (Burden et al. 2012). Education institutions, however, typically remain organized around spatial and temporal considerations such as buildings, timetables, calendars, and internal structures with student learning environments still bearing a worrying correspondence to those used in the previous two centuries.

The principal concern to arise is a need to reconfigure the role of the teacher and their relationship with the student, with the balance of arguments seen in relevant literature indicating a

need to provide the learner with greater control in a digitally enhanced environment. Traditional teacher-led environments, it is concluded, should move from direction and control to facilitation and guidance of learners, a process requiring new skills and knowledge on behalf of staff charged with leading student learning. This has been described as the transition of teacher from “sage on the stage, to guide on the side” (King 1993, p. 30).

Digital Technologies and Learning in Higher Education

The term “digital technologies” in this study refers primarily to multifunctional equipment or devices with Internet connectivity and particularly to devices that are hand-held and portable, a definition which generally means smart-phones and tablet computers. In exploring the opportunities offered through the combination of more traditional Internet access (fixed location) and personal Internet access (mobile), several trends have been identified which institutions of higher education need to explore, evaluate, and possibly adopt as they move forward in a new era. The principal focus of this entry is to explore how student learning could be enhanced through use of appropriate digital technologies.

With portable digital devices now being a core feature of the twenty-first century, this presents the possibility for a fundamental change to education, shifting from passive acquisition of someone else’s ideas to active learning experiences that empower people to inquire, critique, create, collaborate, problem solve, and create understanding (Dede and Barb 2009). With new technologies, information is continually being developed, distributed, and acquired and has become a paradigm that cannot be ignored within educational organizations. Selwyn (2007, p. 91) makes the case that these digital technologies could allow institutions of higher education to reinvent themselves, requiring institutions to make a shift “from the representational capabilities of ICTs (i.e., their ability to represent commoditized informational delivery modes of higher education) to their

more expansionist and relational potentials””. In examining these changes, the American Society for Training and Development (2009) not only reflected the way in which the “millennials” (those born between 1977 and 1997) approach learning but also identified the need to incorporate these digital technologies into the workforce of the future:

The online world has redesigned communication in and outside the workplace; anyone can access almost anything about a topic, so [young people] are now accustomed to accessing multiple open sources of information for solutions. As a result there are more collaborative technologies that have enabled the learning process to evolve from a fixed series of discrete training events into an informal, ongoing experience. Learning can easily occur anytime, anywhere and in a variety of formats. (p. 3)

Digital technologies thus offer the potential for different forms of learning and teaching where academic staff and students can change or transform their perspectives and meanings. The “push-pull” architecture of the Internet invites participation, generating symmetry between production and consumption which is not evident in traditional “broader-casting” mediums such as television or traditional models of formal learning. Tools such as wikis, social networking software (e.g., Facebook), and aggregator services (sites which bring together artefacts from other places) are identified as how educators might shift the emphasis of their teaching by empowering the student to see themselves as knowledge co-constructors rather than passive recipients of information provided. In an era when knowledge is no longer fixed and is subject to challenge on the very public platform of the Internet, students need the skills to explore and synthesize data to determine knowledge and construct meaning.

In this emerging digital age, models of learning based on behaviorism, cognitive, constructivist, and co-constructivist approaches are being overtaken by *connectivism*, an approach first offered by Siemens (2009). Connectivism defines learning as a continual process which occurs in different settings, including communities of practice, personal networks, and work places and allows teachers to shift focus from their textbooks and presentation to the actual student. Knowledge is emphasized by this theory, which stresses the

need to help students gather, access, synthesize, and publish knowledge in print or in online media. This knowledge is no longer under the control of experts, but has been distributed and is accessible to average students. In connectivist-based learning, the role of the teacher changes from that of providing material and presenting lectures to one of helping students create, publish, and share knowledge using Internet-based technologies. Consequently, connectivism suggests giving the learner the control to explore objectives defined by that learner. To facilitate the interaction both synchronous and asynchronous tools are essential as extensions of course environments. With connectivism, active participation is required by all involved in the learning process and matches the aspirations offered by Confucius: “Tell me, and I will forget; show me, and I will remember; involve me, and I will understand.”

Based on the above discourse, we devised a model which seeks to guide learning in higher education beyond self-managed learning and, in this instance, an approach to student learning that makes full use of digital technologies (see Fig. 1, below). As Crook (2008) indicates, the learning process in higher education requires greater self-management of learning as students progress from entry stage to graduation and on to postgraduate level and, in a digital age, engage with fellow students in a collaborative mode. We argue that in addition student learning potential will be enhanced by use of digital technologies that are now readily available and foresee the ultimate aim of such education as being the creation of effective learning environments through interdependency, a state often seen as ideal in the world of work where problem solving and creativity are the product of collaboration rather than independent contributions as suggested earlier (Helfand 2013).

Interdependency is highly valued in the workplace where, within a couple of decades, the tools used in most occupations will be replaced by digital ones (Organisation for Economic Cooperation and Development 2015) and in situations where it is essential that “young people can demonstrate that they not only possess knowledge demanded by employers, but that they can *apply*

Digital Technologies in Higher Education, Learning Challenges,

Fig. 1 Learning in a digital age – Alhafeeri and Male (2015)

that knowledge in different and unfamiliar circumstances” (Mann and Huddleston 2015: 7: original emphasis).

Use of Digital Technologies in Kuwait University

In a previous study, students and faculty teaching staff from the College of Education in Kuwait University were surveyed to assess their access to digital technologies, their capability to use them effectively in support of achieving planned learning outcomes and the implications for change that could emanate from such findings (Alhafeeri and Male 2015). Kuwait University is comparable to other institutions of higher education across the world in that most student learning is organized around face-to-face taught sessions with an expectation that students will undertake further study as appropriate in noncontact times. The organization of student learning in the university tended to follow traditional models, therefore, with academic staff presenting knowledge for student consumption via lectures, seminars, and directed reading. While there was widespread use of computer technology in the university in terms of support for learning, this equipment typically was only used for presentation of material during taught sessions or as a repository for materials through use of a virtual learning environment (VLE). Meanwhile most members of the

university had ready access to digital technologies, particularly portable hand-held devices capable of Internet connection, and were very capable of using them in a personal capacity.

Interestingly, academic staff not only exhibited a higher level of ownership of personal mobile digital devices than the student body, but also perceived themselves to be at least as capable as students in the use of such equipment to support teaching and learning in the college. Students, on the other hand, expressed doubt on the claims made by academic staff of competency and regularity of use of computer technologies in support of learning. A typical taught session, they claimed, consisted of lecturing and discussion without use of technology. The truth seems to be that while academic staff may be skilled and competent in the use of technology at a personal level, it was still not used extensively in face-to-face learning. Furthermore, use of personal devices was not allowed during lectures, even for Internet searches for relevant materials. The scenario witnessed in Kuwait is almost certainly mirrored across the world’s universities.

Discussion and Conclusions

Our previous work suggests that in the current era, higher education academic staff and students are well equipped with personal mobile digital devices and generally consider themselves to be

competent users of such equipment and associated software applications in their personal life. There was little evidence, however, to suggest extensive use of digital technologies to enhance student learning, often with the use of portable digital devices being actively discouraged in taught sessions.

The conclusion to draw from our study in Kuwait University is that ineffective use of available digital technologies is probably more to do with attitude rather than lack of opportunities. The findings from that study seem to mirror the situation that seemingly permeates all phases of education globally in that the technology exists, as does the capability to use it, but the willingness to exploit personal mobile digital devices and associated software applications is limited. The source of such limitation is typically based around intransigence of teaching staff to adapt their practice, a response often disguised through concerns about student safety and the validity of data sources when using the Internet (see, for example, Male and Burden 2014).

As discussed above, however, the potential use of digital technologies in higher education is evolving rapidly and, in the light of globalization and employability, this introduces an imperative for review and change of personal practice and organizational structures to accommodate new possibilities. Higher education institutions in the twenty-first century will need to adapt their strategy and policy regarding student learning to accommodate greater use of personal mobile digital technologies not only because they exist, but also in recognition of the opportunities to provide deeper, collaborative learning among students in the quest to further knowledge. Higher education should not be immune from such influences but will need to take suitable action soon if it is to fulfil its ambition to provide its student body with the knowledge and skills to operate successfully in the digital era.

Introduction

Distance learning, as a label to describe the use of educational and information technologies for instruction and learning, suggests a shortcoming either in the way that the instruction is conceived and delivered or in the appropriateness of the instruction for learning by qualifying “learning” with the adjective “distance.” Were traditional or conventional classroom-based instruction described as, for example, “co-locational learning,” we might be tempted to focus on how learning is influenced specifically by material artifacts such as table and chair arrangements, lighting, ambient distractions, student-to-student proximity, and so on. While these are issues that are worth studying (and are indeed published in journals such as *Learning Environments Research*), they have been regarded as given aspects of learning environments. More contemporary technological interventions to our learning environments, namely digital but prefigured by analog forms, that remove them from material and temporal constraints of classroom-based delivery remain the qualified learning

environments. And perhaps this remains a reasonable arrangement as the complex of instructional considerations we need to consider when thinking about how distance learning differs – though never fully departs – from what we might call traditional classroom learning environments.

Undermining the implied shortcoming of focusing on geographical distance and the tendency to stress the difference in time and place that often marks distance learning, Moore (1992) highlights what he calls “transactional distance” rather than geographic distance, defining transactional distance as the space between learners, instructors, and the instructional design of a course. Transactional distance can either be large (high structure and low dialogue) or small (low structure and high dialogue). Therefore, the transactional distance of a lecture-based face-to-face class, with limited classroom discussion, is larger than that of a tutorial between an instructor and a small group of students facilitated by a cloud-based collaborative application.

This distinction will have important implications when we discuss the strengths and weaknesses of distance learning environments for learning and student engagement. Certainly, having instructors and learners co-located has important implications for learning, including physical proximity, the ability to share activities without technological mediation, the opportunity to actively engage learners and to access, in real-time, whether they are learning or understanding the materials being discussed, and so on. But in other respects, being located in the same place at the same time may not be critical to all types of student engagement. For example, a group of four students tasked with collaboratively writing instructions, whether in class or online, are likely to employ some of the same cloud-based collaborative tools, such as Google Docs, to share, write, and manage their project.

This entry begins with a brief history of distance learning in Canada and the USA and traces some of the developments that have led to its growth over the last several decades. We then discuss the many ways that distance learning is and has been described over the years. One of the challenges with understanding what distance

learning is and is not lies in understanding how researchers label distance learning and how they have traditionally described it. We then review five dimensions of distance learning – of all instructional situations, in fact – describing what research tells us about designing effective instruction. Finally, we describe distance learning and some principle challenges yet to be addressed, touching briefly on massive open online courses (MOOCs) and discussing the importance of that technical trend for education in general.

The History of Distance Learning in Canada and the USA

The history of distance learning is often divided into four stages, beginning with print materials and early efforts with radio and television (the audiovisual stage, 1940s and 1950s). Correspondence courses started in England at the University of London in 1858, with its External Programme (Rothblatt 1988), and Bastiaens and Martens (2000) identified the existence in Germany, in 1840, of correspondence courses on stenography. Distance learning was initially described as correspondence, extended, or distance education and began in Canada several decades later at McGill University in 1889, followed in 1912 by the Universities of Alberta and Saskatchewan who provided “self-study programs” primarily for rural learners dispersed across the Western provinces (Haughey 2013). Distance learning programs in the USA date back to 1892 when the University of Chicago and Penn State University developed their correspondence programs (Pittman 2003). The second stage involves the incorporation of audio and video teleconferencing and the third stage focuses on computer technology capabilities, although the computer is generally standalone with floppy and compact disks (the instructional technology stage, 1980s to mid-1990s). There are, however, some antecedents, such as distance learning materials that were provided via radio broadcasts in 1941 when the Federation of Agriculture, the Canadian Broadcasting Corporation (CBC), and the Canadian Association for Adult Education created “Farm Radio

Forum” for use by home-based study groups that were organized by St. Francis Xavier University and shared with universities nationwide. Later, combining print with audio- and video-conferencing, distance learning expanded in the 1960s and 1970s to reach learners in remote locations, and in 1972, Athabasca University was created to provide distance courses via an open learning system (Haughey 2013). The fourth stage, our current one (the internet stage, circa 1994), involves cloud-based learning management systems with sophisticated course facilities for grading, building learning materials, sharing external resources, assessing student progress, and so on (James and Gardner 1995; Peters 2003; Wisher and Curnow 2003). Numerous historical factors have led to the exponential growth of distance learning over the last two decades. Most importantly, the decreased cost of information and communication technologies has increased user access to advanced collaborative environments. User expectations have also demanded not only that isolated users have access to educational learning opportunities but also that they be accessible at home and in the user’s workplace (Naidu 2003). Unfortunately, some negative forces are also increasing the number of universities in the USA who offer online courses and programs, for example, increased university enrollments, higher tuition costs, and state budget freezes. Despite such problematics, distance education does increase access to educational offerings for some students (e.g., working and older students) and other students are interested in the flexibility of online courses even if those students are located on-campus and have access to on-campus classes (Allen and Seaman 2016). Indeed, distance learning has only begun to capitalize on global audiences able to benefit from its time and location flexibility and lower student cost (Zhang et al. 2004).

Describing Distance Learning

Distance learning has numerous synonyms with varying definitions. Descriptions include online teaching and learning, web-based training, e-learning, computer-assisted learning, online

learning, technology-enhanced instruction, computer-based training, online teaching, flexible learning, distance education, open learning, and instruction and learning with technology. Why are there so many ways to talk about distance education? Many of the different terms used to describe distance learning are merely tailored for different audiences and contexts. After Bernard et al. (2004b), we view distance learning as involving three elements:

- Semipermanent separation (place and/or time) of learner and instructor during planned learning events
- Presence of planning and preparation of learning materials, student support services, and final recognition of course completion by an educational organization
- Provision of two-way media to facilitate dialogue and interaction between students and the instructor and among students (p. 388)

These elements, in turn, have influenced the features of modern learning management systems. Chapman (2005) summarizes these features as consisting of:

- Ability to coordinate course registration, scheduling, learning programs
- Resource management, content integration, repositories
- Material distribution, reporting
- Online conferencing, collaborative tools
- Tracking student accomplishments, learning assessment, learning testing, profiling (pp. 1151–1152)

Bernard et al. (2004a) analyzed and assessed distance learning literature from 1985 to 2002. After examining over 5,000 abstracts, 862 articles were gathered using electronic and manual searches of distance education journals and conference proceedings as well as reference lists of prior distance education reviews. The authors performed the searches using terms such as “distance learning,” “virtual university,” or “distance education” in addition to one of the following: “lecture,” “traditional,” “face-to-face” or

“comparison” (pp. 178–179). Of the articles found, only approximately 25% (232 articles) involved both traditional and distance learning conditions and connected to student achievement, retention, or attitude measures.

With the number of definitions, aspects of technology, and variables at work in distance education environments, it is not difficult to understand there are many challenges to understanding the nature of distance education in toto. Further to the challenges of identifying and defining distance learning, researchers have also identified methodological quality issues such as a high variation in effect sizes.

Orrill et al. (2004) argue that “Literally thousands of studies related to computers and learning have been published during the past three decades”, which poses a significant challenge, they tell us, to those interested in “making sense of the enormous, and growing, body of available research” (p. 335). Berge and Mrozowski (2001), in their review of research in distance education during the 1990s, found that almost 75% of the research involved descriptive studies. So too Nichols (2003) has lamented that “the vast bulk of literature in eLearning is practice-based and is typically presented in a descriptive format” and that “the body of literature appears fragmented and there are few common terms used consistently” (para. 2). In addition to applying inconsistent terminology to their objects of study, researchers have frequently performed comparison studies between online and face-to-face courses although just what constitutes an online course is not always the same (Allen et al. 2002; Álvarez and Kilbourn 2002; Berge and Mrozowski 2001; Bernard et al. 2004b; Larreamendy-Joerns and Leinhardt 2006; Liao 1999; Mehlenbacher et al. 2000). These comparisons have tended to emphasize student performance (determined by course grade) over other interesting issues such as environmental support for collaboration, heightened student engagement and motivation, influence of instructional design and usability, and so on. Even comparative analysis across distance education or e-learning approaches is challenged because, as Pascarella and Terenzini (1998) note, information

technologies are changing at such an accelerated pace that it makes studying them difficult due to the number of variables introduced: “The range and volatility of instructional information technologies not only present serious research design problems, they may also produce a fragmentation that will put knowledge development itself at risk of bogging down in a flood of studies based on single course, single learning settings (let alone single institutions) which have few characteristics in common whether in their independent or dependent variables” (pp. 161–162). Straus et al. (2006) too found that many studies of distance learning were methodologically limited, with small sample sizes, low response rates, convenience samples versus random assignment, and so on, a finding which they noted had been observed by other researchers (e.g., Phipps and Merisotis 1999). They found, additionally, that courses described as distance learning contained very different levels of media use, including one-way versus two-way tele-training, chat and asynchronous support, self-study versus collaborative group support tools.

Still, in the final analysis, many researchers appear to agree that distance learning is similar or comparable to traditional instructional contexts. Shachar and Neumann (2010) provide this summary after their meta-analysis of 125 distance learning studies, noting cautiously that distance learning occasionally outperforms traditional instruction as well and that this finding complements previous research (e.g., Bernard et al. 2004; Davies et al. 2010; Means et al. 2010; Newlin et al. 2005; Pang 2009). Notably, despite evidence suggesting that distance learning leads to higher learning outcomes (e.g., examination scores or course grades) and engagement in students, researchers often go out of their way to avoid challenging the primacy of traditional instruction. Erdogan et al. (2008), for example, conclude “This kind of interpretation would not mean that web based instruction is an alternative to classical instruction but web based instruction is an alternative solution to the education problem. . . .” (pp. 42–43).

In these discussions, the distance in distance learning remains a central focus for discussion. However, drawing attention away from the

technologies that mediate our learning environments for a moment, we can shift our vantage to explore some other attributes that shape these learning environments. In order to focus on the *learning* in distance learning, it is useful to describe in detail the five dimensions of distance learning, or of any instructional situation in fact, to help us attune ourselves differently to distance education environments.

Five Dimensions of (Distance) Learning

If we acknowledge that distance learning has less to do with the geographic distance between instructors and learners, as Moore (1992) allows us to do, then we can begin to see distance learning as a particular kind of instructional situation, admittedly one that relies on a technology-augmented connection between instructors, instruction, and learners.

The five dimensions of all instructional situations are learners (who have particular cognitive, biological, affective, socioeconomic, and material attributes), tasks (analyze the poem, combine these liquids, solve this physics problem), social dynamics (listen to a lecture, discuss the readings in small groups, debate two sides of an issue), instructional activities (learning objectives, rubrics for performance, methods for evaluating learning), environments (lecture halls, study halls, seminar rooms, labs), and artifacts/materialities (chairs, laptops, smartboards, scientific equipment) (Mehlenbacher 2010).

And just as all instructional situations call for planning, bringing together external resources that augment learning, establishing clear criteria for implementing instruction and for measuring learning outcomes, so too must instructors attend carefully to some of the marked differences between teaching at a distance and teaching in a face-to-face environment with little or no technology beyond traditional pencils and paper, tables and chairs, and whiteboards. Online instruction, importantly, transforms and reorganizes space and time and the classroom, at least traditionally speaking, feels as though it has disappeared initially.

Learners, Their Backgrounds, and Their Knowledge

Learners are perhaps the most studied of the attributes of any instructional situation, online or off. If we chose, instead, to focus on teaching methods or technological innovations employed in the classroom, we run the risk of de-emphasizing the central goal of any instruction, that is, to facilitate learning.

Research highlights that the background and knowledge our students bring to the classroom strongly influences how easy it is for them to learn new material, integrate it with their existing understandings, and apply what they have learned in new contexts. Importantly, anticipating our learners, their backgrounds and prior knowledge, self-regulatory skills, communication skills and readiness for learning is critical to the design of effective instruction. Moreover, how we account effectively for student diversity and difference is certainly a research area that requires additional attention, especially given the increasingly globalized learning audiences that instructors routinely interact with. We can now anticipate learners across the lifespan, with a range of cognitive and physical abilities, and different motivations, styles for learning, and metacognitive orientations. Different learners will meet new instruction from different understandings of the domain in study, with a range of skills and anxieties related to technology, and different textual and visual information capabilities.

An effective distance learning environment will tend to be highly goal structured, with instructors paying careful attention to student learning processes and progress throughout the course. The challenge with online courses is that learners need to be more intrinsically motivated than students in face-to-face settings where set scheduling, collegiality, instructor presence, and environmental proximity all contribute as extrinsic motivations. Hiltz and Shea (2005) found that students who have a strong internal locus of control (feeling able to accomplish their goals online) and who feel positive about their technological abilities, in addition to participating regularly in distance learning courses, tend to do better than

students who are more passive or disengaged. Naturally, instructors will need to establish whether learner passivity is a feature of poor instructional design or a motivational issue that resides in the learner.

Learning Tasks and Activities

Tasks designed to teach students not only *how to do* something (e.g., write an essay) but also to teach them *about* something (e.g., history of ancient Greece) are often ignored when researchers talk about designing instruction. One of the reasons that learning tasks tend to receive little attention in higher education is that procedural knowledge tends to be left to training and, in higher education, instruction is designed to focus on epistemic matters. Another reason that tasks may receive less attention than they should when we think about teaching is that many instructors are not very good at explicitly setting learning objectives for their students and their instructional materials. Researchers such as Bloom (1956) and Biggs (1999) provide useful ways of thinking about instructional learning objectives (which can move from comprehension, application, analysis, synthesis, through evaluation or identification, description, analysis, through theorization). Learning objectives explicate instructional goals using specific language that can be measured for success or failure. Students will be able to describe, evaluate, compare and contrast, apply, differentiate, and so on. And, in turn, instructors can then measure whether their students have learned to do these things or tasks.

Properly conceptualized, learning tasks and activities ultimately unite learner behaviors, facilitate social dynamics both online and off, inform instructional activities, and clarify what types of assessment are most effective given the assignment deliverables. For this reason, many instructional designers strongly recommend that learning tasks and activities be as authentic to specific contexts as possible. Moreover, after Herrington et al. (2003), it is critical that instructors design learning tasks that are as authentic to the skills and knowledge they hope learners will master as

possible. Authentic tasks and activities are connected to real-world activities, are ill defined or complex, facilitate seeing issues from different perspectives, highlight collaboration, and can have different outcomes and competing solutions.

An effective distance learning environment will have well-designed content and, particularly, clear instructions and an easily accessible schedule for completing instructional tasks and activities. Instructional content that highlights not only what instructors expect their students to learn but also provide opportunities for learners to synthesize and articulate covered materials also help students develop their metacognitive strategies.

Social Dynamics in the Digital Classroom

Allen et al. (2002) used the search terms “distance learning,” “distance education,” and “satisfaction” on SocioInfo (Index for the field of Sociology), ComIndex (communication publications), Psychlit (psychology publications), and the Educational Resource Information Clearinghouse (ERIC), in addition to conducting a complete review of *Distance Education* and the *American Journal of Distance Education* to identify approximately 450 peer-reviewed articles for analysis. Although their primary goal was to compare distance learning courses to conventional ones, the authors also identified several research themes that characterized the corpus of articles under review. Topics reviewed included the effects of the modality of communication (video, audio, and written) and of the presence or absence of interaction in setting (none, one-way limited, or fully interactive). Not surprisingly, Allen et al. (2002) found that the greater the channel of communication and instructor-student interaction, the greater the effect on student satisfaction.

An effective distance learning environment will provide alternative forms for communicating collaboratively with other students and also for supporting communication between instructors and learners. Importantly, online materials must be well designed and goal- or criterion-directed, employing thoughtful sequencing (from simple to complex instructions), encouraging easy response

and quick feedback, in addition to some elaboration and exploration on the part of learners. Although tools for collaboration abound, many instructors new to distance learning forget that online learners tend to feel somewhat isolated in their learning and long for meaningful interactions that increase their sense of belonging in a learning community. Collaboration tools that support both synchronous and asynchronous interaction heighten learner belonging and, by default, contribute to students who engage the materials more deeply and who rely on other learners in the instructional situation as well as the instructor.

Instructor Activities

Instructor activities with distance learning involve all planning, implementation, design, testing, and assessment efforts built into a course to help motivated and engaged learners manage their learning experience. Students who are not motivated to learn or who have limited experience working online are likely to focus on surface learning activities (e.g., where are the readings, what activities are due, where are they described, and what resources are available to help meet the course expectations). Instructor beliefs, knowledge of the subject matter, experience of teaching online, the amount of instructor presence they are able to present, and thoughtful feedback they are able to provide all contribute to online learners' engagement with online instruction.

Successful online instructors tend to operate more as consultants or facilitators for their students, guiding them as they encounter new information and processes and, importantly, orienting them to the opportunities and challenges of learning online. Critical to online learning is the creation of a safe learning environment where students are encouraged to work cooperatively and collaboratively with others (Bonk and Dennen 2003), in discussion lists, shared posts, collaborative projects, and in sharing class expectations and processes with others. Although many instructors have limited training in how to integrate visuals into their textual instructions, research suggests that visuals are powerful learning aids. Schnotz

(2005) suggests that instructors thoughtfully build coherence and continuity into their modular instructions, taking care to design their materials to anticipate different learner reading ability and prior knowledge about the course content (pp. 60–63).

Notably, even experienced face-to-face instructors may require some training before they can effectively transfer to distance learning instruction (Petherbridge and Mehlenbacher 2007). This is not entirely surprising given the host of knowledge that most instructors need to bring to any teaching situation. Not only must instructors have some expertise in subject matter and in pedagogy, but they must be sensitive to what the research tells us about how students learn and also about how online instruction influences and undermines traditional models of instruction. Online, for example, learners are much more likely to become disoriented and disengaged if they do not hear back from instructors regularly; moreover, learners tend to skip and scan online information much more than they do print materials (Mehlenbacher 2003). Instructors also need to understand not only how to facilitate discussion and written discourse but also how to manage instruction and course sequencing online; many of these activities in face-to-face instruction are tightly integrated with classroom discussion but, in distance education, must be attended to as well. Summers et al. (2005) found, for example, that the same instructor teaching online and face-to-face classes received lower satisfaction ratings online for the usefulness of the instructor's explanations, and the instructor's enthusiasm, openness, and interest in student learning (p. 244). Hale et al. (2009) add to this finding, noting that online students found their instructor's established rapport and personal interest in them was lacking. Distance learning alters the response that learners have to behaviors that are almost identical except for whether they occur in a classroom or online. For this reason, online instruction benefits immeasurably from careful presentation of content and questions, efforts to focus instruction, attention to student contributions, summaries, and well-articulated assessment and feedback.

Learning Environment and Artifacts

A number of challenges with distance learning that are difficult to manage relate, expectedly, to technological design: screen resolution, display area, and aspect ratio all contribute to different levels of engagement and learner receptiveness (Selber et al. 1997). Print literacy has a considerably longer history than computer-based information and the accelerated rate of display options and sizes is influencing learner reading and writing patterns in ways that are difficult to anticipate, and in ways that seem to be evolving.

Additionally, even powerful learning management systems are constantly evolving and integrating new tools and processes. Iverson (2000), in describing typical classroom contexts, notes the effective classes *place*, that is, learner location in classes, groups, around tables, face-to-face or adjacency, individual and shared workspaces, and so on. Conventional classrooms are equipped (with computers, whiteboards, work arrangements, and structure), and they encourage spatial reconfiguration and learner movement. Finally, conventional classrooms employ well-developed modes of communication, oral, structures, dialectic exchanges, and summarizing. These are elements that must be designed and built into distance learning spaces.

Most importantly, distance learning operates in several potential modes on a continuum from on-site learners and on-site facilitation and support, through on-site activities and virtual support, virtual activities and face-to-face support, through fully digital display, discussion, and interaction. In the middle of the continuum, instructors operate in blended environments and the research on these environments is only beginning to outline the strengths and weaknesses of working in these developing structures (Van Eijl et al. 2005).

Finally, Bransford et al. (2000), Bereiter (2002), Jonassen (2008), and Mehlenbacher (2010) highlight the transformative power of technology to enable, extend, or augment professional activities, genres, and artifacts. Various described as cognitive tools or conceptual artifacts, these tools extend human abilities to design, predict, analyze, and present artifacts demanded

of them by their professional transactions and practices. Cognitive tools do not replace previous print-based objects with digital ones (e.g., books as portable document files) but, instead, shape and extend existing activities in new ways (Weston and Bain 2010).

Paying Attention to Distance Learning

The landscapes for distance learning are changing in ways that are difficult to predict with consequences that are even harder to anticipate. Dutton and Blank (2014) note, for example, that between 2003 and 2011, the percentage of British online publics who used their smartphones or tablet devices to access the internet had jumped from approximately 10% to 50%, similar to growth statistics for the USA, which has 95% of Americans using smartphones, up 35% since 2011 (Pew Research Center 2018a). In addition, more and more households boast higher broadband connections suggesting that the need for reliable, high speed internet access has increased over the last decade and is viewed as “essential” (Pew Research Center 2018b). Yet interestingly, current internet users are much more likely to access the internet while on the move or outside of work or the home; alternative locations for access include another person’s home, the library, in an internet café (all cafés, now, essentially). What the implications are for a learner population that accesses distance learning materials on the move, between locations and, frequently, while multitasking or engaged in an additional task, remain unclear.

In addition to the attentional difficulties of reading on the go, researchers have identified numerous information processing challenges that include fatigue and multitasking in addition to the influence of different sizes of displays and font sizes. It is also well documented that internet activities can amplify cognitive errors; for example, confirmation bias where users tend to find support for their own points of view and group-think, where individuals tend to follow members of the group (Tarkoff 2018). Moreover, students asked to engage others in open-ended discussions of course subject matter tend to offer surface level

contributions that reach agreement (i.e., “good post!”) rather than providing elaboration, taking issue with contributions, or questioning the positions taken by their classmates. Some of the hesitation to contribute authentically or to facilitate lively discussion can be traced to the seeming permanence of written contributions (in contrast to oral give-and-take) and some has to do with the user sense that posting is a one-way activity without a face-to-face audience to engage with. Another aspect of this challenge might be that students are merely satisficing, that is, doing what is minimally required to engage with the instructional situation. This is a natural inclination on the part of learners, particularly online learners, and must be addressed actively by instructors who are virtually present and engaged with learner discussions and contributions.

And then, 2012 became “The Year of the MOOC” (Pappano 2012), which described the conception and popularity of what was described as a “campus tsunami” that represented the future of the educational system (Leckart 2012). MOOCs, or massively open online courses, promised to democratize education “bringing quality learning content to people of any age, in any corner of the world for a fee – if not for free” (Brooks 2012). Coined in 2008 by Dave Cromier (University of Prince Edward Island) in response to an online course designed by George Siemens (Athabasca University) and Stephen Downes (NCR Canada), the first MOOC involved 25 tuition-paying students at the University of Manitoba and 2,300 general students who took a “Connectivism and Connective Knowledge” class for free (Downes 2008). The course interactions consisted primarily of Rich Site Summary (RSS) feeds, Moodle discussions, blogs, and 2nd Life synchronous online meetings, technologies that all existed and were regularly used at the time to reach unprecedented numbers of students and, most importantly, MOOCs brought discussions of the role of distance learning in higher education to the public conversation. Moreover, MOOCs attracted a lot of funding (from the William and Flora Hewlett Foundation, the Andrew W. Mellon Foundation, the Bill & Melinda Gates Foundation, and Google), all poised to capitalize on

what was seen as a transformative trend in higher education (Kolowich 2012; Weissmann 2012).

But the bubble broke, or at least it appears to have deflated considerably. And part of the reason why can be determined by looking at the history that led up to the educational online revolution. During the 1980s and 1990s, American universities had increasingly privatized and, as the professoriate dropped, universities saw a sharp rise in adjunct or contingent instructors. In addition, universities were increasingly under attack for being too expensive and for serving the student population poorly (Bousquet 2008; Hoeller 2014; Wallerstein 2012). MOOCs appeared to offer unprecedented opportunity for learners who otherwise could not afford to attend Ivy League universities, even though their retention rates were often as low as 5% and their pedagogical structures were rather traditional (e.g., web course materials, audio- and video-based lecture recordings, student-driven assignments and participation, and auto-grading or peer review-based assessment). Critics began to highlight these issues and to note that MOOCs reinforced the hierarchy between students who can and cannot afford the on-campus experience. Moreover, MOOCs inadvertently supported the critics' belief that education should continue to be defunded, stressing credentialing as the primary mission of universities. Finally, MOOCs continued to serve the growing adjunctification of university instruction, running the risk of further reducing student-faculty interaction, a cornerstone of campus education.

It is problematic to conclude that MOOCs are a failed distance learning enterprise, but initial promises that they will reshape education in total are exaggerated and unsupported. MOOCs are designed to have high transactional distances between instructors and an enormous number of learners (cf., Moore 1992), a pedagogical structure that is similar to learning from large lecture-hall classes with breakout study groups. Although these structures can certainly lead to successful learning experiences, researchers have found that high transactional distances limit student

engagement and learning (Bolliger and Halupa 2018). Many MOOCs, therefore, are not revolutionary pedagogy. In addition to studying the sociotechnical context that is informing the design of online and conventional instruction, future researchers will want to extend their studies of learners to include informal learning contexts and international learners as well as how socioeconomic issues influence the teaching and learning that students encounter and experience.

Distributed Collaboration in Project-Based Learning and Its Assessment in Next-Generation Learning Environments

Eric Hamilton¹ and Veera Kallunki²

¹Pepperdine University, Malibu, CA, USA

²Centre for University Teaching and Learning (HYPE), Faculty of Educational Sciences, University of Helsinki, Helsinki, Finland

Introduction

Distributed Collaboration in Project-Based Learning and Its Assessment Advances in technology historically have altered the ability of individuals to communicate with and to collaborate with one another (Hollingshead et al. 1993; Walther et al. 2015; Liao et al. 2018). The implications and opportunities for education have been and will continue to be profound (Collins and Halverson 2018). This entry introduces the nascent area of IT-mediated collaborative learning activities that focus on creating a product or an artifact and that involve virtual teams of individuals who work together, both synchronously and asynchronously, from geographically distinct locations (Hamilton 2018; Hamilton and Owens 2018; Lee et al. 2019). While contemporary society is accustomed to the anywhere/anytime nature of Internet-mediated communication, formal and informal education models have not yet substantially incorporated research-based approaches to virtual, project-based collaboration in differing geographic locations. While a later section notes some important exceptions to this generalization and furnishes a light taxonomy of collaboration forms, information technology has ushered in new forms of connecting students both through communication with each other and through the content of what they co-create.

This entry focuses on and advocates widespread adoption of such collaborations more broadly in the design of next-generation ecosystems, especially as they involve two additional

characteristics. The first is that the collaborations entail direct, interpersonal interactions between the geographically distributed participants, interactions that are incidental to the artifact itself. That is, the participants become personally acquainted, often forming friendships, usually over videoconferencing or other IT-enabled means. The second characteristic involves virtual collaborations that cross cultural, national, economic, generational, academic background, or linguistic boundaries. We refer to those here simply as boundary-crossing collaborations (see Niemi and Multisilta 2016).

The potential for such IT-mediated collaboration, including cross-boundary forms, to function as *a natural, abundant, and seamless aspect of next-generation school learning*, is intertwined with crucial and exciting technology-enabled areas currently unfolding in education research, innovation, and the learning sciences.

In the near term, these areas include the makerspace movement (Sheridan et al. 2014; Fontichiaro 2016), the ascendancy of both computational thinking (Paul 2016) and design thinking (Liedtka et al. 2013; Leinonen et al. 2014), more context and place-aware learning tools (Sharples 2015), project-based learning and modeling (Rouvrais et al. 2006; Tsai et al. 2015), triological approach for learning (Paavola and Hakkarainen 2014), and advances in education data science (Williamson 2017).

Over a longer term, current research in augmented and virtual reality (Dunleavy 2014), artificial intelligence and adaptive learning environments (Gerard et al. 2015), and more mature and sophisticated conventions on massive data capture and use will occupy more prominence.

The next section briefly discusses the growing emphasis on collaborative learning in education research before delving into the potential for virtual, project-based collaborative learning to occupy a prominent place in future learning environments. Such strategies for learning veer far from practices that lend themselves to traditional testing. The entry closes with a discussion of how computationally intense techniques adapted from social network analysis can be employed for settings such as collaborative project-based learning.

Such techniques can allow educators and designers to visualize student and team progress more holistically and across a range of heterogeneous indicators, including traditional indicators of academic performance but including socio-affective and cross-cultural growth, which are interrelated in project-based virtual collaboration and must be assessed in connection with one another using advanced data methods. Such IT-enabled innovations in learning analytics will permit more telling and interconnected pictures of how individuals and groups progress epistemically and of key malleable variables that shape their progress.

IT Mediated Collaborative Learning

The rationale for learning to be researched more fully as a social phenomenon, along with the construct of a joint problem space (Teasley and Roschelle 1993), has been widely accepted at least since the early 1990s. In addition to a theoretical rationale, the exploits or accomplishments of virtually every sector of society arise from collaborative activity (Hesse et al. 2015) and rightfully impels more attention to collaboration in primary and secondary education.

The term *collaborative learning* is subject to varying interpretations. For present purposes, we adopt the definition by Hennessy and Murphy (1999), who treat collaboration as referring to students “actively communicating and working together to produce a single outcome, talking and sharing their cognitive resources to establish joint goals and referents, to make joint decisions, to solve emerging problems, to construct and modify solutions, and to evaluate the outcomes through dialogue and action” (Hennessy and Murphy 1999).

The importance of IT-supported or computer-supported collaborative learning has been documented across academic domains, in part through high-impact visionary (e.g., Teasley and Roschelle 1993; Koschmann 1996; Roschelle 2013) and summative (e.g., Dillenbourg et al.

2009; Jeong and Hmelo-Silver 2016) (e.g., Dillenbourg et al. 2009; Jeong and Hmelo-Silver 2016) articles, including specific domains of school learning (e.g., McKeown et al. 2017). The research community emerging in the 1990s in computer-supported collaborative learning now holds biannual conferences and eventually created the *International Journal for Computer-Supported Collaboration* (iJCSCL) in 2006 (Stahl et al. 2006). That literature largely (but not exclusively) involves student collaborators, who interact in physical proximity, such as in a school, home, or museum.

Distinctions Between Project-Based Virtual Collaborative Learning Forms

Project-based learning in virtual or distributed collaborations is uncommon in primary or secondary education, with some exceptions. The emergence of wikis or other Web 2.0 social media forms in the 2000s fall somewhat outside this consideration of projects that represent defined tasks to jointly complete a project artifact. Internet-mediated project-based learning generally entails completing digital artifacts. Collaboration through second life was one of the earliest exemplars (Wagner 2008) of a family of applications involving simulations, virtual worlds scenarios, or their creation (e.g., Barab et al. 2005; Barab and Dede 2007; Dede 2009). Among the most prominent contemporary examples involve the collaboration forms for Scratch programming (Maloney et al. 2010) or for Minecraft (Müller et al. 2015; Niemeyer and Gerber 2015). Each of these examples, however, represent instances of where the product of the collaboration represents an artifact embedded in the digital context in which it was created, such as a virtual space or a wiki. Project-based collaboration in virtual reality settings will become more common in the near term and will also fall into this category (Greenwald et al. 2017). Each of these also can engage learners who can choose to remain relatively or virtually anonymous to each other.

Distributed Collaboration in Project-Based Learning and Its Assessment in Next-Generation Learning Environments,

Fig. 1 Cultural and historical activity theory schematic (Soegaard and Dam 2012)

Sharing Design Priority on Learner Community with Artifact Production

Adopting a cultural-historical activity theory (CHAT) framework may help to illustrate an important difference between collaborations situated within online containers (e.g., Minecraft or a virtual world) and projects meant to yield artifacts and to require more active interpersonal connections. CHAT depictions distinguish between the actors, actions, objects of actions, and conventions or rules of action. Fig. 1 schematic appears in various forms in social sciences literature (Greeno 2016) and functions well as an organizing or descriptive tool for group activities. A common premise of the learning sciences is that activity mediates learning. Rather than preceding or preparing for activity, in other words, learning—especially project-based learning, for example—is embedded in activity systems. Mapping Fig. 1 schematic to the IT-enabled project-based collaborations may help to situate collaborations where participants may remain anonymous or obscure versus a more active personal interactions role in co-producing team artifacts.

In the former case, the primary object of collaborative learning is the artifact. An alternate perspective is one in which the connections between the collaborators, i.e., the personal interactions and emergent community, are of equal or higher importance as an object of the collaboration (Hamilton et al. in review). In this family of collaboration types, strong dyadic and community formation share or exceed priority with artifact production as a collaborative goal or object of

the activity. Cross-cultural, international, ethnically diverse, or other boundary-crossing dimensions amplify considerations when designing such collaborations.

Interestingly, those dimensions may address an apparent shortcoming in virtual versus local collaborations. While virtual and local project-based learning may each be considered knowledge building through social interaction (Von Kotze and Cooper 2000), some researchers have concluded that virtual collaborations entail less robust social interactions than those that are local or co-located (Kreijns et al. 2013). One conjecture for this is that social and emotional factors such as trust, identity with a community, and interpersonal relationships that are at the center of face-to-face collaboration are less salient in virtual settings (Fischer et al. 2013). Indeed, collaborations that permit relative anonymity by participants, such as wiki contributions, Minecraft making, or virtual world communities, may entail active and intense interactions around the artifact but require little socialization or interpersonal exchanges. Collaborative scripting as a means to scaffold interactions has been the subject of a sizable strand of research in the CSCL community (e.g., Dillenbourg and Tchounikine 2007; Fischer et al. 2007; Strijbos and Weinberger 2010; Kreijns et al. 2013; Wang and Mu 2017), but that work primarily focuses on optimal designs to facilitate collaboration, i.e., is artifact-oriented rather than focusing on relationship building. In the CHAT framework, scripts have instrumental value to scaffold activity and progress toward completing

the artifact. An alternative direction is to create conditions that more explicitly scaffold relationships between participants, by which they transition from acquaintances to a blend of active friendships and collegial boundary-crossing (e.g., international) connections.

IT mediation, especially through videoconferencing for the synchronous aspects of the collaboration, has proven crucial in such participant-centered collaboration (Eagan and Hamilton 2018; Lee et al. 2019).

IC4 Project

Figure 2 depicts videoconferencing between students in four countries in research that the US National Science Foundation (NSF) supports through its *Advancing Informal Science Learning Program*. This research effort is called the International Community for Collaborative Content Creation or IC4 (ic4.site; Hamilton and Culp 2016). It involves digital media-maker teams of elementary through college-age students in five demographically distinct US locations, along with synchronous and asynchronous peer collaborators in Africa, Europe, Asia, and Mexico (Kallunki and Hamilton 2017; Hamilton and Owens 2018).

This type of diverse setting is one in which it is possible to investigate the conjecture that cross-boundary virtual collaborations can have robust social interactions that rival those of face-to-face collaborations. Research focusing on virtual teams confirms that knowledge-sharing and collaboration positively impact social trust (e.g., Erdem and Ozen 2003; Alsharo et al. 2017) in adult workforce settings. One conjecture we are testing at the secondary school level is that it may be that being able to observe and interact closely with a peer from a different culture, country, or economic stratum is non-threatening from the cultural safety of one's own location. It appears that collaboration from one's own home or school environment, for example, can effectively neutralize potential inhibiting anxieties, while trust and friendship relationships take form in completing a task. This primes and scaffolds new understandings about both the shared task and about one's peers. That sense of safety can help induce not

only comity but also deeper appreciation, joy, and celebration both of shared humanity and of the gravitational allure of instructionally well-designed projects. The field of boundary-crossing virtual collaboration in precollege project-based collaboration, at least as far as it prioritizes active interpersonal interaction, is relatively scarce, despite important work referenced above in the development and testing of collaboration scripts.

With the language and frameworks for this field still unfolding, the question of whether cultural safety from a distance neutralizes inhibiting anxieties that otherwise emerge in face-to-face settings is indeed still conjectural. Consistent with this possibility, however, we have found repeated confirmation of the existing finding that school-based collaborative learning can generate creative energy and distribute high-valence affect among its participants (Chua et al. 2012). IC4 participants, for example, such as those appearing in Fig. 2, repeatedly cite surprise and pleasure at meeting and interacting with peers from other cultures and nationalities (Kallunki and Hamilton 2017). The IC4 design prefaces any interaction between participants with self-introductory videos or online presentations each creates. Students meet each other virtually and share their interests, especially in the science, technology, engineering, or mathematics (STEM) areas that are the focus of their joint projects. These projects take several forms, and the virtual context in which the students collaborate are referred to as digital makerspaces (Hamilton and Culp 2016; Eagan and Hamilton 2018). These initially included co-constructed videos, and then video remixes using the online Sway platform, robotics projects, and coding.

MoViSTEM Project: Finland-USA

The IC4 project originates in part from a prior Finland-USA collaboration, called the Science Across Virtual Institutes (SAVI) network (Hamilton 2012). The SAVI network had 16 research projects in Finland and in the USA in an effort to carry out significant advances in education and the learning groups (<http://www.innovationsforlearning.net>) (e.

Distributed Collaboration in Project-Based Learning and Its Assessment in Next-Generation Learning Environments, Fig. 2 Boundary crossing: collaboration team in NSF-funded Informal Science Learning project (IC4), representing multiple ages, cultures, countries, and backgrounds. From top left: Students in a California school

making a stringed instrument and testing its octaves for sharing with partners in the USA and Kenya; students from Finland, Kenya, and the USA share a session on Scratch programming and videoconference work session with students in Brazil and USA

g., Rowe and Shernoff 2014). One project in this NSF, Academy of Finland, and Business Finland (earlier TEKES)-funded collaboration was a Mobile Video STEM Inquiries (MoViSTEM) project. MoViSTEM represents asynchronous online collaboration between students in the two countries generating digital storytelling that has been used as a part of science learning in comprehensive schools in Finland and the USA. In this project, small groups of students created digital stories by recording videos, uploading the clips to the online environment where the videos were edited, sharing them with others, and remixing them with

annotations. In this way the focus was both on sharing and learning. In the project, collaborative communities were formed at two levels: local communities in classrooms and global communities in the virtual environment. The global communities worked as small groups or pairs alike to mentoring pairs: high school students from the USA commented on and asked questions about the digital stories created by the younger Finnish students. The collaboration was organized as an asynchronous activity so that commenting happened generally on the day after the sharing of videos. Finnish students had positive experiences of community:

the feeling that someone “there behind the big sea” was watching and commenting their videos motivated the students. Being able to use English in a real context played a role in creating a positive view of collaboration. In addition, linguistic boundary crossing took place on both sides, since the Californian students wanted to communicate in Finnish and used Google Translate for this purpose. In general, the findings from the Finnish side indicate that an online collaboration including digital storytelling experience has an impact on the use of English as medium for international communication and the establishment of networking and collaboration with peers both online and locally (Vivitsou et al. 2017).

MoViSTEM Project: Sino-Finnish Collaboration

In a subsequent phase of the MoViSTEM project, digital storytelling experimentation was carried out between China and Finland (funded by Business Finland). The project connected four primary schools in Finland and in China (Vivitsou et al. 2017). This project, where classes of students from both countries created digital stories locally about shared topics, was also implemented in a form of asynchronous collaboration. After creating the digital stories, the students shared the stories in an online environment (edvisto.com), and the stories were then watched and commented on in both countries separately. In both countries watching digital stories from the other country has been welcomed with curiosity and excitement.

Other examples include schools that partner with area businesses to engineer solutions to real-world problems, Internet-based exchanges around robotics, and platforms for collaborative video and music authoring and mixing. Beyond specific examples, though, we envision virtual teams of students in next-generation school learning environments in settings similar to – and more sophisticated than – current workforce settings in which virtual, heterogeneous, distributed professional teams are commonplace.

Sociocultural Development and Academic Growth as Mutually Reinforcing

The domain of virtual team collaborations across cultural, ethnic, national, or other boundaries is extremely promising for next-generation school learning environments and for far-reaching social and economic well-being. Research suggests that distributed collaboration settings can foster both group and individual growth in areas such as self-regulated learning (Panadero et al. 2015) and group and individual problem-solving capabilities (Hmelo-Silver 2016). The intuitively sensible proposition that *group or team* collaboration can intrinsically contribute to social or intellectual maturing of the individual may be even more far-reaching, due to an equally intuitive finding that what we refer to as cross-boundary collaboration in schools can routinely generate socio-cultural and affective energy, performance motivation, curiosity, and social trust (Hamilton and Owens 2018; Lee et al. 2019).

In practical terms, these prosocial dynamics can materially contribute to individual intellectual rigor and academic achievement. Collaborative discourse implies intersubjective meaning-making, i.e., the formation of shared meaning (Suthers 2006). Learning that results from dialog and other interactions between collaborators entails designing, creating, and developing artifacts that challenge participants to learn more and to step outside their earlier proximal zone to a higher plane of quality (Multisilta 2014). That drives the need to clarify, retrieve, and build new knowledge. Collaborative discourse drives the cognitively powerful process of self-regulation and self-explanation (Crippen and Earl 2007; Mitchell 2009; Nokes-Malach et al. 2013), leading the learner to acquire the perspective of, and make sense to, the boundary-crossing collaborators (Lindgren 2009). In distributed and digitally supported collaborative environments, learners are both content producers and consumers. When creating project artifacts, students must not only isolate the most relevant content but also the most effective way to teach their peers through their artifact. They must assess critically,

give feedback, and validate the knowledge they find. This method allows or requires students to work together (Pea and Lindgren 2008; Lindgren 2009).

Collaboration benignly coerces participants to jointly represent, elaborate, test, expand, and refine their STEM thinking (Wong et al. 2002) at both the individual level and at the level of their social and distributed cognition. This extends self-regulation to its analog at the group level, socially shared regulation (Järvelä et al. 2015) – a construct representing a team analog to self-regulation, involving sizing up group tasks, identifying roles, knowledge needs, and purpose. It creates new channels for grasping, comprehending, sharing, and deeply integrating discovery, knowledge, and skills into a young person's early life experience and future expectations of self and society. It also reflects increased appreciation for the intertwined nature of socialization, affect, culture, motivation, and learning (Immordino-Yang and Damasio 2007). Cognitive and collaborative competencies reinforce each other in ways that create a forcefulness for personalized school learning (Spector 2014). This forcefulness is undertheorized, underdesigned, and underappreciated for its potency as an asset in the design of high performance and prosocial education for next-generation learners.

More generally, distributed project-based collaboration offers opportunity to the next generation to invent new conditions for interaction that are not defined by geography. An illustration that appears out of place may instead convey some of the potency of the distributed collaboration in ways that address fractures in our broader global society that fall too often along cultural and geographical boundaries.

Historical Perspective from the USA. One of the most contentious and difficult aspects of the civil rights movements in the 1950s into the 1990s in the USA has involved school desegregation. The physical relocation of students through forced busing reflected tools available to courts at the time to address the racial segregation norms in US schools. The record of the school desegregation enterprise was mixed, with multiple factors undermining success (e.g., Failer et al. 1993; West

1994; Wells et al. 2005). An important study at Columbia University, however, traced the socio-cultural experience of students involved in the integration effort, unpacking an importantly positive and often overlooked aspect of this entry of US history. Beyond the social strife surrounding physical relocation of students, a pervasive finding in the study involved the socio-affective and academic richness and growth experienced by learning alongside peers from different racial and economic profiles (Holme et al. 2005).

Designed to address economic inequality, desegregation action was ordered by courts with tools in education that were available at the time. But the tools for bringing students of different backgrounds together in learning, and to experience the cross-cultural and socio-affective richness that was once only possible through strife-riddled physical relocation, are different now. Virtual presence dramatically inhibits the power that physical geography has imposed to separate and instill distrust and conflict throughout our history. Virtual collaboration in project-based learning and artifact production will not replace court-ordered remedies to racial conflict. Coupled, though, with technology-enabled tools to foster interpersonal interaction, it will offer opportunity for almost unbounded replication and expansion of some of the most salutary effects of physically relocating students across boundaries.

Indeed, we have found in the IC4 project discussed earlier that developing communities of students who collaborate on projects virtually across cultural, economic, and national boundaries *routinely elicits a sense of cross-cultural curiosity and embrace* (Hamilton and Owens 2018). IC4 is a network of school-affiliated “digital makerspace” clubs in six countries, for middle and secondary students who collaborate in producing videos, robotics demonstrations, coding, or other digital artifacts that can be created and shared over the Internet. How each student expresses cross-cultural curiosity and embrace in this context varies by individual and their culture, but indicators of enthusiastic openness to peer collaborators from other countries are salient elements of thousands of interviews, written

reflections, and recorded collaborative activities – a data corpus in which there are zero references or mentions of antipathy or uneasiness at such collaboration. Distributed project-based learning, especially over time zones or national boundaries, requires many layers of orchestration, nuance, and logistical coordination. But getting kids to appreciate and enjoy and seek to understand peers who differ greatly from them appeared to be the easiest and most natural component of the process (Hamilton and Owens 2018).

Additionally, it appears that online collaborations between students, especially including videoconferencing, effectively primes for affectively positive and academically compelling in-person subsequent collaboration, a phenomenon that university researchers experience regularly in academic collaboration but that is not structured into K12 education. And the IC4 project has repeatedly observed the “helper’s high” phenomenon (van der Linden 2015; Lee et al. 2019) of increased sense of well-being and confidence by students who treat science and math as subjects to help others understand, rather than as subjects that they have to succeed in a test on. Such dynamics can characterize next-generation learning environments.

Assessment of Individuals and Teams in Complex Collaborative Environments

Information technology advances have enabled profoundly important innovations in learning and education. These in turn require reconceptualizing student and group assessment. Digitally mediated project-based learning environments that enlist or develop a range of interrelated competencies and that yield digital artifacts obligate processes that extend far beyond traditional academic assessments. The degree to which an individual can help size up her or his role in a group project, create new ways of looking at the project, or facilitate retrieving information or building knowledge all bear on cognition and learning. In the example of the IC4, student teams produce videos to teach or explain science and mathematics concepts or create presentation

remixes. These types of projects center on topics typically associated with academic disciplines. They are affected not only by prior knowledge in those disciplines but other factors such as expressive skill, representational creativity, self-efficacy, and ability to take the perspective of others.

Connecting skills and dispositions from a complex setting such as those involved in distributed collaborations is beyond the capability of any pre-digital assessment system. IT-enabled learning analytics promises to have the transformative potential for assessment that IT has for learning.

One new analytics methodology called epistemic network analysis (ENA), developed by David Williamson Shaffer and his team at the University of Wisconsin in the USA, provides insight into how IT systems can help to reconceptualize what assessment systems can deliver. ENA is a quantitative ethnographic approach (Shaffer et al. 2009; Shaffer 2017) that originates in, but then extends beyond, the data visualization techniques of social network analysis. In social network analysis, individuals typically represent nodes on a graph, and connections between them are edges of the graph. Rather than using nodes to represent individuals on a graph, ENA can graph at the student level modeling a network of connections between elements of an individual’s epistemic frame. An epistemic frame can be considered a gestalt or ensemble of heterogeneous factors, such as complex reasoning skills, beliefs, social connections, or values that an individual can bring to any activity (such as collaborative problem solving). Each of these elements can be represented as a node on a graph, with the strength of association between any two elements of an epistemic frame differing from student to student or group to group.

From a collection of such networks (i.e., the networks of some set of individuals), ENA creates an ENA space. These networks can be viewed in the ENA space, individuals or groups can be compared, and differences between individuals or groups (e.g., between students in different countries) can be quantified. The process uses mathematics like principal components analysis or factor analysis. However, while factor analysis isolates a list of possible latent variables through

load factors based on subject responses, ENA identifies latent patterns of connections between epistemic frame elements by measuring temporal proximity – how often the elements appear near each other. Such ensembles (collections of heterogeneous factors) can also include data points captured in collaborations (such as conversational flows, pauses, affective valence indicators, or dialogic content sophistication). This permits visualization of trends in both individuals and groups. Data resulting from collaborative exchanges can be treated as input streams that then yield graphs or visualizations that highlight relationships in group or individual learning. For purposes of illustrating connections between factors, data cited in Lee et al. (2019) appears in Fig. 3. Based on a series of constructs identified in forerunner projects (Hamilton 2015; Hamilton et al. 2016), a series of codebook of constructs was developed. They were identified as important aspects of student experience in media-making

projects between peers in different countries and appear in Lee et al. (2019). Interviews with IC4 members in different groups revealed contrasts: mathematical centroids for codes attached to interview utterances in Group A and Group B are marked with a dotted rectangle and reflect different group dispositions. The first group’s emphasis on content confidence, ability to see the perspectives of others, and social disposition contrasted with the goal orientation and self-directed learning constructs that frequently came up in the second group. The construct most prominently shared by each group was self-awareness. This illustrates the potential value in the ability to visualize salient connections and epistemic commitments collaborators make in their projects. ENA can be considered as a philosophical marker for the type of learning analytics that will serve practices such as distributed project-based learning, because of its emphasis on treating data holistically. Analytics typically require forming a

Distributed Collaboration in Project-Based Learning and Its Assessment in Next-Generation Learning Environments, Fig. 3 Network graphs model discourse patterns between two student groups, identifying construct

connections. Centroids and their confidence levels furnish visual comparison of distinct discourse patterns between the groups

narrative based on integration of originally separate large data streams that are captured in disaggregated form into the data ecosystem. Future systems that support personalized learning may indeed successfully create actionable and data-driven narratives from such streams. (A comprehensive survey of the learning analytics software education market, however, shows repeated tendency in commercial products to focus exclusively on data capture with virtually no attempt at alignment with sound educational practice or theory (Sarmonpal, in submission)). The approach that we believe most promising for consideration in synthesis and design is one that captures data as it is connected to other aspects of an individual's epistemic frame. This distinctive paradigm essentially suggests the potential for connecting heterogeneous data points at the point of capture to make sense of the learning design.

Research Directions

The complex world the next generation will inhabit requires complex skills of collaboration and parallel-processed competencies that far exceed what contemporary schooling entails. It will require sufficient design sophistication in learning environments to help prepare students for occupations that neither yet exist nor have even been imagined. The paths to authentic academic success in next-generation learning environments should be wider, more plentiful, and more pervasively experienced than in current and past generations.

Ironically, and happily, the researchers and practitioners on our planning team, along with the broader literature, have uncovered a compelling truth mentioned earlier about the potential for astutely designed collaborative learning: it fosters rigorous academic success even – and especially – among those who otherwise might be considered middling or mediocre in academics.

Those emerging professional competencies also include design of projects and raise important design questions. Virtual collaboration in project-based learning differs substantially from local teamwork. What design principles optimize virtual projects, especially as new enablements in

areas such as artificial intelligence, virtual reality, and augmented reality become more readily available? Within the context of IT-mediated quantitative ethnographies, how do trust, self-efficacy, help-giving, complex reasoning, and ability to see the perspective of one's collaborators affect one another? To what degree are these variables malleable in ways that can mutually reinforce and optimize the other variables? To what degree can they encompass or integrate complex combinations of both global and so-called micro-competencies for next generation and mid-century learning, such as those promoted by UNESCO's advocacy for major paradigm shifts in curriculum and learning (Marope 2017)?

The digital makerspaces or virtual project-based learning scenarios this entry reviews involve intense and crucial IT enablement in each of the areas of communication between students, the type of artifacts that they produce, and the advanced learning analytics that can help visualize individual and group progress, as Fig. 3 depicts.

In addition to questions above about project design, one of the most significant questions for research in this domain appears earlier. Why is it, or how is it, that children appear to have such fluid or easy-going ability to function across demographic boundaries when their presence is virtual rather than physical? To what degree does virtual presence prime or scaffold high-trust and productive face-to-face collaboration? These questions are important not only educationally but sociologically. Is there a path by which education innovation can create new conditions not only for greater intellectual or academic success but also for different ways that individuals from diverse or different populations engage with one another?

These types of settings also obligate research questions about the shifting role of the teacher. The technical skills in organizing digitally mediated collaboration around projects are far afield of the teacher preparation that many current educational practitioners have experienced.

There are no panaceas in education, and the vast majority of the world's population lives in a condition of educational crisis (Jeevan and Townsend 2015; World Bank 2017). Yet it is

arguable that never has society been on the cusp of such quantum jumps in the improvement of educational experience. It turns out that technology has enabled this potential, but the potential itself turns on ways that individuals can relate to one another more powerfully in shared ventures in the pursuit of solving problems or new knowledge.

The History of e-Books

Books and the way they are read have not changed much over the past centuries, since the first known manuscript written in the thirteenth century called the *Dresden Codex*. Unsurprisingly, books began changing in form, access, and content just before entering the millennium in 2000. Since then, books have been transformed into electronic books or e-books, which provide fast, easy, and downloadable reading matter. Digesting written materials in this form can be more convenient and portable.

The e-book was born in 1971 when the idea to save space and digitize books took root, and a digital library called the Gutenberg Project was set up (Lebert 2009). In 1974, the Internet first went live through the Internet Protocol (IP) which was later referred to as Transmission Control Protocol or TCP/IP, introduced by Vinton Cerf and Bob Kahn. The discovery of connecting oriented links and datagram between hosts provided the platform needed for e-books to flourish. Research centers and universities were among the first to take a foothold in the new field of the Internet in the 1980s. After the Web was created by Tim Berners-Lee in 1990, after 3 years, the first browser Mosaic was created, and from 1994 onward, access through the Internet began to spread rapidly.

The first e-book was available in July 1971, as e-text #1 of Project Gutenberg, a visionary project launched by Michael Hart to create electronic versions of literary works and disseminate them worldwide. In August 1998, Hart wrote in an email interview, "We consider e-text to be a new medium, with no real relationship to paper, other than presenting the same material, but I don't see how paper can possibly compete once people each find their own comfortable way to e-texts, especially in schools" (Lebert 2009). Peter Schweitzer, inventor of the @folio project, the prototype of a reading device, wrote in an email interview: "The luck we all have is to live here and now this fantastic change. When I was born in 1963, computers didn't have much memory." He added, "...by the combined effect of the Moore Law and the ubiquity of networks, we will have instant access to works and knowledge. We won't be much interested any more on which device to store information. We will be interested in handy functions and beautiful objects" (Lebert 2009). In terms of taking book access further forward, in the sixteenth century, Gutenberg allowed anyone to have print books for a small cost, while in the twenty-first century, Project Gutenberg would allow anyone to have a digital library for free (Lebert 2009).

Whether the hard-copy book is in jeopardy or not is arguable, but the great challenge to conventional print books is obvious; the twin

developments of digital text and the Internet have brought about major and rapid advances in all areas of our lives. We are now accustomed to writing and producing documents electronically, communicating electronically, storing and retrieving information electronically, and, increasingly, accessing it anywhere on a wide range of devices. In this context, the humble print book can feel rather anachronous, and students will rightly expect at least basic electronic access to their course books in the same way that they can access almost everything else they need freely, immediately, and online. As students' demands change, a transition to the print book's successor, the e-book, therefore seems both essential and inevitable.

Through some clear examples, it is possible to see how e-books have been incorporated successfully into educational practice, enhancing the learning experience for students, particularly students with disabilities and for distance learners. Through success stories that reflect well on e-books, such as exciting partnerships with research institutes, the development and promotion of an e-book app, the creation of an open living book, and new collaborations with e-book publishers and vendors to provide access to e-textbooks to students, all these examples show us that such practices are reaching the level of maturity needed for widespread adoption.

In the twenty-first century, universities are at the forefront of embracing the opportunities brought about by new technologies as well as understanding and overcoming their limitations. University leaders and managers concern themselves with developments that align with institutions' strategic priorities, deliver competitive advantage, improve teaching and research performance, reduce costs, and enhance value for money. E-books have the potential to engage with all these strategic priorities. Following the successful integration of e-journals into the academic workflow, e-books promise universities to enhance students' educational experience, enrich research resources, and streamline services. They have greater potential to transform the reader experience than e-journals, and yet they have experienced a long and difficult birth, suffering

from digital rights management, integration, discoverability, and functionality challenges.

Definitions of E-Book

The E-book is generally defined as text that is available in an electronic format such as Microsoft Word documents, text document (.*txt*), Hypertext Markup Language document (.*HTML*), or Extensible Markup Language document (.*XML*) (Hawkins 2000; Ormes 2002; McKnight and Dearnley 2003; Vidana 2003). Some definitions combine both the electronic text and the electronic reader device that are required for an e-book to be read (De Abrew 2001; Lynch 2001; Goh 2002; Grant 2002). Other definitions relate the conversion from print to electronic aspects of e-books, as printed text converted into digital format, to be read on a computer screen (Saurie and Kaushik 2001; Desmarais 1994). Connaway (2003) defined an e-book as a publication that is characterized by an electronic format, utilizing Internet technology to make it easy to access and use. Rao (2003) defined an e-book as “text in digital form, or book converted into digital form, or digital reading material, or a book in a computer file format, or an electronic file of words and images displayed on a desktop, note book computer, or portable device, or formatted for display on dedicated e-book readers.”

E-book readers as we know them have been around for almost a decade now. In 2004, the Sony Librie was the first e-ink device to be released commercially, although it was only available in Japan. Amazon only followed in 2007 with the first-generation Kindle, which was only available in the United States. By 2018, there was a huge variety of e-book readers available, and the problem was choosing between them. E-book databases are making their way into libraries through popular providers such as netLibrary, Books 24 × 7, Questia and Ebrary (Mullin 2002; Connaway 2003).

E-Books in Education

More and more computers connected to the Internet were available in schools and at home in the

mid-1990s. Teachers began exploring new ways of teaching. Going from print book culture to digital culture was changing relationship to knowledge, and the ways both scholars and students were seeing teaching and learning. Print book culture provided stable information, whereas digital culture provided “moving” information. E-books have the potential to involve three key strategic priorities common to most universities: to heighten the student experience and academic outcomes within an increasingly competitive environment; to drive innovation in learning, teaching, and research; and to help to use space and human resources more effectively and efficiently (Fyfe 2014). Enhancing the student’s experience is clearly a key strategic driver for all universities, sharpened by ever increasing global competition for well-qualified students.

In this age of technology, students can embrace the technology instead of avoiding it. From classrooms to libraries, students and educators are increasingly opting to use e-books because of the many advantages they give, such as the convenience, weight riddance, saving trees, and bookmarking, highlighting, annotating, and search capabilities. Libraries, on the other hand, have increasingly turned to providing e-book services due to problems such as diminishing budget, limited shelving space, increasing cost of new building and resources, the rising cost of repair or replacement of books, growing demand from users for electronic resources, rising cost of inter-library loan services, and the demand to support distance or distributed learning needs (Ismail and Zainab 2005). E-books have satisfied users’ desires for immediacy and provided an easier and convenient access, especially for remote users (McCarty 2001; Snowhill 2001). E-book subscriptions have solved libraries’ recurrent problems of lost, or stolen, or damaged books (Ardito 2000; Connaway 2003). Furthermore, the provision of e-books does not require unpacking, processing, and shelving and eliminates the extra time previously required to handle and process them before they can be used (Grant 2002; Helfer 2000). Features for handling e-books are also becoming more user-friendly, making it fairly easy for readers to browse, navigate, able to

view graphics and videos or submit keywords, and undertake full-text searching within a book or a collection of books (Snowhill 2001; Grant 2002).

E-Books at Tertiary Level

Academic libraries have traditionally played an important role in providing access to and disseminating information across learning and research communities. That role has now been extended to facilitating access to electronic resources such as e-journals and e-books through innovative technologies. Although both publishers and libraries are unsure about the future for and the impact of e-books, there is increasing awareness that e-books demand further attention (Vassiliou and Rowley 2008). Studies show that librarians are only partially aware of students' perceptions about e-books and that there are conflicting priorities among students, faculty, and librarians (Soules 2009).

Folb et al. (2011) assessed the use and factors affecting use of e-books by all patron groups of the Health Sciences Library System. A total of 871 patrons completed the survey, with an approximate response rate of 18.5%. The results indicated that library e-books were used by 55.4% of respondents and that, in general, respondents preferred print for textbooks and manuals and electronic format for research protocols and reference books. In spite of little promotion, 65.5% were aware of the e-book collection.

E-book popularity has been growing steadily over the past 5 or 6 years (Ramaiah 2005). Charles Sturt University, a major provider of distance education, has taken up the challenge of moving away from the traditional print-based method to electronic delivery of instructional material (Messing 1995). The Open University (OU) in the United Kingdom has also moved to an electronic paradigm in adopting the e-book as one of their primary learning materials. In Malaysia, the Open University Malaysia (OUM) also followed the trend by providing a digital collection in addition to more than 8500 volumes of books in its main campus and learning centers nationwide. The OUM's digital library provides access to

more than 40,000 titles in e-books and 18,000 titles in e-journals, respectively. Other than OUM, Malaysia Multimedia University, the University of Malaya, and the Universiti Sains Malaysia are among the universities that provide e-book services in their campus libraries. The newly opened Kuala Lumpur Library has also purchased and subscribed to e-books, while other institutions such as the National Library provides e-book services, although not on a very large scale (Primalani 2004).

On the one hand, results from some studies suggest that involvement with computers, through the use of electronic content and other new technologies, can promote positive attitudes toward learning and higher achievement among learners (Espinosa and Chen 2001; McCreary et al. 2001). Studies also showed that computer-based learning tools lead to significant gains in learners' performance in reading, mathematics, computer knowledge, and grammar (Shields and Behram 2000). On the other hand, regardless of the vast amount of e-books available and the great potential of e-books in education, findings from Abdullah and Gibb (2006) revealed that the majority of their respondents (60%, 823 out of 1372) have never read an e-book. This result conforms to the findings by Chu (2003), Gunter (2005), Perry (2005), and Bennett and Landoni (2005). They found that most of their respondents had not read an e-book.

This interesting finding leads to the question of whether the phenomenon is the same in other countries. This article will explore a country case – the situation in Malaysia. Specifically, the question will ask whether students have yet to read an e-book. Within this context, a case study aimed to achieve the following objectives:

- (a) To determine the extent of e-book usage among Malaysian students.
- (b) To identify the impacts of e-books on the Malaysian students.

The Case in Malaysia

A survey was conducted with students from various educational institutions and levels as the target

group using both field and online surveys. The field survey was held at the Universiti Teknologi PETRONAS, and the online survey was distributed to other university students from around Malaysia. Collectively, the survey obtained 666 complete responses. The respondents were given questions which addressed the usage of e-books, impacts of the e-book to them, and the limitations of the e-book. Besides the Universiti Teknologi PETRONAS, respondents came from a range of other educational institutions. Among them were the Universiti Malaya, Universiti Teknologi Melaka, Politeknik Sultan Azlan Shah, Universiti Kuala Lumpur, and a secondary school.

Demography of Respondents

The majority of the respondents were female with 56%, while males were 46% (refer to Fig. 1).

Explicitly, 372 respondents were in the tertiary level, 287 were in the pre-tertiary level, and 6 were in secondary school (refer to Fig. 2). The highest number of respondents were in Engineering, Science and Technology (258) followed by Finance, Management and Commerce (96), Education (81), and one respondent was from Accounting (refer to Fig. 3).

A majority of the respondents (83%) reported that they were aware of the e-book before the survey was conducted, while only 18% of them were not (refer to Fig. 4).

E-Books Among Students, Advancements in Higher Education, Fig. 1 The respondents' gender

E-Books Among Students, Advancements in Higher Education, Fig. 2 The current institution of the respondents

Usage of e-Books

Figure 5 shows the frequency of e-book usage. The frequency of e-book usage in a month was reported at 35%, followed by 29% weekly and 14% daily. Surprisingly, 22% reported that they had never used an e-book before. The postulation that the e-book is not a popular tool used by Malaysian students could be concurred, since the results show that only about one third of the respondents use the e-book in a month. It is unexpected to find students who reported that they had never used the e-book, especially considering that all schools are equipped with computer laboratories.

Laptops (42%) are the most preferred access device, giving the respondents a better self-reported experience (refer to Fig. 6). Following closely are smartphones (33%), tablets (17%), and desktops (8%). Although the smartphone was the least preferred device to use for e-book utilization due to its display screen size which smaller than other devices (Kowalczyk 2017), the smartphone fared much better in this study than the desktop. Maybe sometimes size does not matter; some other factors may be affecting the respondents' preferences.

The respondents were asked about the location where they accessed e-books. A majority of the respondents use the e-book almost anywhere (32%) followed by both at school and at home (27%). When separated, those who used the e-book in school were reported at 24%, while at home it was 17% (refer to Fig. 7). As anticipated, since the preferred device is the laptop and the smartphone, the location of usage could be anywhere. But, for the 17% of the respondents who

E-Books Among Students, Advancements in Higher Education, Fig. 3 The respondents’ field of study/education stream

only use the e-book at home, this could be due to the device or limited connectivity.

When asked what the e-book is usually used for, 69% say it is for research purposes followed by searching for the latest information (17%) and entertainment (13%) (refer to Fig. 8).

When asked specifically as to why the e-books were used, 361 of the respondents said that they used the e-book to search for some topic using a keyword search on the net. Other than that, 159 respondents said they intentionally used an e-book because physical books are too expensive,

while 50 respondents said that the physical books were unavailable on the shelf. However, 85 respondents said that they used e-books to search for books which are only available in electronic form (refer to Fig. 9).

The respondents were asked how they read the e-book. Most of them read the e-book online (49%), while almost the same percentage downloaded the e-book and saved the book on their respective devices (48%) (refer to Fig. 10). Only 3% had the book printed on paper. It could be assumed that sufficient connectivity resulted in

Malaysian students using the e-books through online reading (at home or at school) or downloading them. Also, it could be assumed that the respondents utilized large capacity devices.

Availability wherever and whenever were the two most exclusive positive characteristics associated with uses of e-books. This statement was strongly agreed to, and agreed to, by 30% and 50%, respectively, of the respondents. Although a majority understood the capability of the e-book, 17% of them were unsure (refer to Fig. 11).

Before this survey, have you heard of e-books?

E-Books Among Students, Advancements in Higher Education, Fig. 4 The respondents’ acknowledgment of e-book prior the survey

Impact of e-Books on the Respondents

A majority of respondents were of the opinion that e-books were more practical and serve to better understand certain topics. As shown in Fig. 12, 58% of them agreed, and 13% of them strongly agreed. However, 23% of the respondents were unsure and 5% disagreed. This finding indicates that the e-book was received well by the students overall, and it can be a reliable source of information, especially when it comes to understanding subject matter.

As shown in Fig. 13, a majority of the respondents agreed (51%) and strongly agreed (23%) that after guidance given by their teacher, they were able to master their syllabus. This indicates that the e-book has a positive effect on the teaching and learning of an academic syllabus. It also indicates that a teacher’s role could offer an advantage for the respondents. However, it is also noted that 21% are undecided about the e-book’s effect.

In Fig. 14, 52% and 20% of the respondents agreed and strongly agreed, respectively, that they get fast and thorough feedback, response to or review of their performance in their learning process. However, 23% were unsure of the e-book’s capability, while 5% disagreed and 1% strongly

E-Books Among Students, Advancements in Higher Education, Fig. 5 Frequency of e-book usage

disagreed. This finding indicates that a majority of the respondents are familiar with the functions or features of the e-book, and students can use the e-book to monitor through self-assessments.

Figure 15 shows that a majority (41% agreed and 39% strongly agreed) of the respondents

reported that e-books helped to lighten their schoolbag and also helped to maintain good body posture. A small percentage of 15% were unsure of this advantage, while a smaller percentage of 5% disagreed. This finding shows how using e-books in school could have positive effects on body posture of students using them.

E-Books Among Students, Advancements in Higher Education, Fig. 6 The preferred e-book device

The Limitations of the e-Book

As shown in Fig. 16, 176 respondents agreed that physical books provided them with reading pleasure rather than the e-books. A total of 171 of the respondents preferred physical books to the e-book because of hindrances such as low memory capacity, low battery life, and low screen resolution and color. A total of 144 respondents preferred physical books over the e-book because of Internet accessibility. This finding seems to challenge the opinion that Internet access at schools or universities in Malaysia is sufficient to support the usage of e-books. Overall, 121 of the respondents expressed that they preferred physical books rather than e-books because there is nowhere for them to jot down notes on the pages of e-books. Perhaps, what could be deduced here is the respondents are not exposed to e-book launchers that offer sidenote features such as those offered by Kindle (Purdy 2010).

E-Books Among Students, Advancements in Higher Education, Fig. 7 The place that the respondent mostly use the e-book

A follow-up question required the respondents to answer a “yes” or “no” answer with an option to respond with “not sure.” As shown in Fig. 17, a

majority of the respondents (51%) were of the opinion that the device was the main hindrance of using the e-book, while 33% disagreed, and 17% were not sure. The implication of the response is that e-book devices still have room for improvement. This suggestion echoes Waller (2013). It was found that the reader device had limited battery life and therefore had to be charged; the device may also face technical problems and not offer access to the e-textbook platform.

Finally, using the e-book requires some technical skills, especially when handling the e-book launcher device. As shown in Fig. 18, 38% and 12% of the respondents agreed and strongly agreed, respectively, that the lack of skills in handling the device and advanced features of the e-book encroaches the time they have set aside for reading. On the other hand, 18% and 5% of respondents disagreed and strongly disagreed with the above statement, while 28% of them were not sure.

E-Books Among Students, Advancements in Higher Education, Fig. 11 The respondents opinion on the handiness of the eBook

questions may give brief pointers for lecturers or university administrators upon implementing the use of portable electronic e-book devices:

1. The use of e-books in the classroom involves a number of different personnel: lecturers, university administration, and technology specialists. Is there any collaboration among them to ameliorate content presentations of the syllabi with the e-book readers?
2. Technology is the most vital prerequisite in introducing e-books in class. Thus, it is essential to install specific software and hardware as a fundament in preparing higher institutions with the technology of e-books. So, are these technologies readily available? Do lecturers

E-Books Among Students, Advancements in Higher Education, Fig. 12 The Impact of e-book on helping user to get better understanding on the topics

E-Books Among Students, Advancements in Higher Education, Fig. 13 The impact of the e-book as an effective method of mastering the syllabus after teacher guidance

- and tutors alike have knowledge and skills about e-books?
- How do colleges and universities provide instructions and manuals to pupils who are not IT savvy; are English for specific purpose pupils; or have special needs, such as autistic and Asperger syndrome? How can e-books support educators in helping these groups of students?
 - E-books may not have a long shelf life if not regularly and properly maintained. Is the maintenance of e-books properly planned for and

implemented? If they are, who is responsible for it? Will the service be readily available? Would it be affordable to the larger numbers if it were to be implemented more widely?

A Framework for Using e-Books as Textbooks

With the wide range of benefits that e-books bring to teaching and learning, e-books offer lecturers a teaching tool that can assist them in effectively

E-Books Among Students, Advancements in Higher Education, Fig. 14 The e-book gives fast and thorough feedback of learning performance

E-Books Among Students, Advancements in Higher Education, Fig. 15 The impact of e-book on users' health

conducting teaching and learning sessions in the classroom. Nevertheless, this article also acknowledges that e-books can never replace the fundamental function of lecturers, irrespective of the extent of e-book technological advancements. Furthermore, the effectiveness of the student's education depends on the types of feedback, direction, and encouragement that can only be provided by lecturers who

possess the knowledge and exude passion and enthusiasm. The use of e-books as textbooks is suited to today's modern learning environment; the education system has entered a new paradigm to keep pace with the needs of the emerging green environment. To provide a framework which can be utilized when using e-books as textbooks in the classroom, a framework of using technology within

E-Books Among Students, Advancements in Higher Education, Fig. 16 The limitation factors that made the respondents choose physical book over eBook

E-Books Among Students, Advancements in Higher Education, Fig. 17 The respondents’ opinion on the device limitation as the main drawback of e-book application

K-6 Programs in the National Reading Panel Report 2000 [10] can be considered. The framework consists of five general capabilities as detailed below.

Presenting Various Presentations of Information and Activities

The extensive functions of e-books include many types of auditory or visual materials – including speech, text, music, animations, photographs, or videos – alone or in different combinations. Apart from that, e-books can link and combine different types of representations such as pictures with

sounds, oral readings with written text, videos with subtitles, or other combinations that could strengthen teaching and learning. They also provide enormous flexibility, allowing students to set the rate of speech, decide whether written text should also be read aloud, choose the language presented in text and speech, or decide whether to repeat the presentation.

Facilitating the Evaluations of Students’ Work

The capability of presenting information and activities in various formats also means that

E-Books Among Students, Advancements in Higher Education, Fig. 18 Handling skills and advance features of the device encroaches reading time

e-books can accept a variety of inputs from students, ranging from mouse clicks to written text as well as spoken words. It also consists of programs that permit students to check and mark their work, thus indirectly nurturing them to become independent learners. Since effective e-books are highly capable of recording and organizing information, as well as reporting that information in multiple formats, this function can be used to inform lecturers' instructional decisions and to make documenting students' progress much more efficient.

Automating Feedback for Students

Since e-books ease evaluation, they should also be interactive as well as able to portray user-friendly interfaces to ensure effective instruction. For example, when students respond to questions or read aloud, they need feedback to know whether they are correct; instruction to help them learn more; and opportunities to engage in additional work at appropriate levels to further their learning. When tasks require simple inputs, such as selecting from presented options or typing a word, e-books can be programmed to immediately evaluate each response and provide appropriate feedback with the addition of thorough explanation and description on particular answers.

Most importantly, aside from presenting a personal or individual progress report, e-books can be programmed to adjust the tasks presented, based on feedback from previous performances.

Providing Scaffolds for the Learning Process

Besides interactive instructions, it is vital for e-books to provide flexible support for the students' learning processes, especially in building vocabulary. Most e-book programs provide the ability to highlight text sections and take notes, and some even add the ability to create drawings within the book. All of these features can increase a student's comprehension of and attention to a given work. Some e-book programs have interactive dictionaries, providing just-in-time learning, that allow users to select any word within the e-books and get a definition instantly, have the definition read aloud, or request an instant translation to another language. This too serves as an attraction for a new modern definition of learning compared to the traditional chalk and talk method by lecturers in the past.

Ensuring Sustainable Resources of Knowledge

Providing scaffolds for the learning process should also be supported by fostering sustained

development of knowledge. E-books can contribute to this continuous effort through maximizing the availability of knowledge while reducing the numbers of trees cut down to produce printed books. Every year about 200,000 tons of paper are produced from four million trees for the publication of textbooks. This accounts for approximately 20% of the total paper used in the book publishing sector. Malaysia currently has 20 public universities, 24 polytechnics, 37 public community colleges, 33 private universities, 5 foreign university branch campuses, and about 500 private colleges. Besides that, various other educational institutions from the United Kingdom, the United States, Australia, Canada, France, Germany, and New Zealand offer twinning and franchised degree programs through partnerships with Malaysian colleges and universities (Ministry of Higher Education 2009). The number of trees cut down to produce textbooks to cater for all universities, and college students could easily amount to hundreds of thousands.

Recommendations and Conclusion

This entry has not only highlighted that the convention of e-books among university students is still not encouraging, but it has also exposed that it may seem that both students and lecturers would need more time to fully explore and take full advantage of using e-books in the classroom. Classroom administration is eased through the use of e-books and their application to manage the class and monitor individual students' activities and performance. Students' development can be closely and conveniently monitored, documented, categorized, and accessed. It is suggested that information technology (IT) support staff are required in each university to monitor all the e-books and to ensure the e-books function optimally. Similar to a desktop or laptop which requires periodical servicing, these e-books need an in-house technician since the users are new, are not accustomed to use e-books for education purposes, and are in a large number. The general opinion on the usage of the e-book among university students is that students will utilize the

e-books if their lecturers and the university provide a suitable e-book environment. Further research is suggested to determine the perceptions of the lecturers on the use of e-books in the classroom. The emergence of e-books as textbooks among university students requires all parties (i.e., lecturers, technologists, parents, and even policymakers) to deliberate on adopting and adapting themselves to the use of e-books. While e-books will not replace printed books in the near future, they will definitely be used to complement printed books. In classrooms, lecturers and students will start to value the convenience and accessibility of e-books. Technologists can expand e-book usage among a large number of university students by creating awareness on e-book usability. Parents will be exposed to the latest developments in education technology. Indeed, the introduction of e-books in education could be a jump-start in promoting a highly e-literate society. The suggested framework above may also suit a country's policy, but the development and publishing process of textbooks into e-books may be different from one country to another. The process may be subjected to policies made by the Ministry of Education of a specific country to possess the full copyright of publications.

Definitions

Baker and Yacef (2009) define Educational Data Mining like a “discipline, concerned with developing methods for exploring the unique types of data that come from educational settings, and using those methods to better understand students, and the settings which they learn in.”

The definition of learning analytics prosed by Siemens (2011) is “the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs.” It could be useful to precise the level of the analysis; Buckingham Shum (Buckingham 2012) proposes macro-, meso-, and microlevels that refer to the range of the target. Macro-level targets cross-institutional analysis, meso-level is the institutional level, and microlevel is the individual level. Learning analytics use different computer, mathematics, and statistical method and technics according to the kind of analytics (descriptive, diagnostic, predictive, and prescriptive). The results of learning analytics are tools to assist human stakeholders

who constitute the learning system, like students or teachers.

Educational Data Mining and Learning Analytics Research Position

The theme of *Educational Data Mining* first appeared during the ITS (*Intelligent Tutoring Systems*) conference in Montreal in 2000 (Gauthier et al. 2000). But it is really in 2005, with the first workshop on EDM held in Pittsburgh in conjunction with the AAAI (*Association for the Advancement of Artificial Intelligence*) conference that the theme started to take off. Most of the research works presented at that time were led on data coming from ITS (Koedinger and Corbett 2006). The first state-of-the-art work was published in 2007 by Romero and Ventura (2007) and was followed by the creation of the yearly EDM conference in 2008 and of its associated journal, the *Journal of Educational Data Mining* (JEDM), in 2009. In parallel, and independently, the *Society for Learning Analytics Research* (SoLAR) was founded in 2011 with its associated yearly conference, LAK (*Learning Analytics and Knowledge*), followed in 2014 by its own journal, the *Journal of Learning Analytics* (JLA). Finally, the AIED community has been structured for three decades around two alternating biyearly conferences, AIED (*Artificial Intelligence in Education*), which became yearly in 2017, and ITS (*Intelligent Tutoring Systems*), as well as a journal, IJAIED (*International Journal of Artificial Intelligence in Education*).

Very early on, the two new communities (EDM and SoLAR) have acknowledged each other and the differences that exist between them, mainly in the background of its lead members (semantic web for LA, educational software for EDM), the analysis techniques they mostly use (social network analysis for LA, more machine learning for EDM), and their overall goal (empowering learners and teachers while leaving them in charge for LA, automated adaptation by the computer for EDM). Those key differences are well summarized in Siemens and Baker (2012). The principal difference between Educational Data Mining and

learning analytics is that results (algorithms, methods) are used directly by computer learning system in the case of EDM while the target of learning analytics still the humans: “EDM has a considerably greater focus on automated discovery, and LAK has a considerably greater focus on leveraging human judgment” (Siemens and Baker 2012).

Through an analysis of the social networks of the conference reviewers and journal authors from the AIED, EDM, and LA community, Labarthe et al. (2018) have shown that Siemens and Baker’s call has been heard, as more and more scientists are at the frontiers between the communities. The research themes however remain clearly distinct, as shown by the keyword analysis of the journal abstracts proposed by Labarthe et al. (2018), with an emphasis on automation and prediction for EDM and visualization for LA. However, these are the different pieces of the same puzzle: enhancing learning experience through technology. Predictive models, sequential patterns, analysis of social interactions and textual analysis coming from techniques in artificial intelligence are ongoing topics about Educational Data Mining, while dashboard and prescriptive analyses to assist human decisions are ongoing topics about Educational Data Mining.

Definition

Learning with geomedia encompasses all forms of learning that use implicit or explicit geospatial referencing using a coordinate system across a wide variety of topics, subjects, pedagogical aims, and learning environments. Technically, this is nowadays mainly based on Geographical Information Systems (GIS) that allow to digitally collect, to store, to analyze, to visualize, and to communicate spatial data. The relevant GIS nowadays are ubiquitous and immersive, implemented in online services and cloud databases and often accessible through mobile handheld devices, e.g., smart phones and tablets.

Within the field of geoinformation/geomedia and learning, four major strands of thought can be identified that follow distinctly different pedagogical aims. These are a technical/industry argument fostering the development of a geospatial workforce, a Spatial Thinking argument that supports the development of Spatial Thinking skills along the paradigmatic settings of the spatial approach and therefore linked to science education, a Spatial Citizenship approach derived from critical cartography and participation and therefore the humanities, as well as a Spatially enabled Learning approach that uses geoinformation as system to support learning processes across subjects through almost complete spatial referencing of learning materials and outcomes as a spatially organized learning suite.

Introduction

The Technological Domain and the Geoinformation Society

Human action takes place in space, produces and reproduces space and place taking into account societal and physical rules, and appropriates space (Werlen 1993). As means of action, humans have been using geoinformation for centuries. A description of a specific place, explaining a route to someone else, using the sun and stars for orientation, using signposts or producing a sketch map to depict the supposed location of a treasure all contain geoinformation. This type of geoinformation usually consists of a location that is more or less exactly defined, as well as attribute data detailing specific qualities of the location, area, or route described. Thinking of a verbal description of the last holiday, people usually look into where it was, what the specific qualities of the place were, how they got there. Early rulers both in Asia and Europe kept track of their subjects in terms of spatialized data for tax collection and the reproduction of power structures using territorial strategies. All these actions clearly can be “put on the map” using their location.

Starting in the early to mid-twentieth century, additional technologies became available for mapping agendas. These include first aerial photography developed for the military in reconnaissance flights leading to a distanced view of the earth’s surface from above during World War I, which transformed the view of the world into an additional bird’s eye perspective. Later, with the advent of additional computing possibilities, GIS were developed for peaceful purposes in Canadian forestry, profiting from the possibility to map, store, and analyze data of large tracts of land. While the technology was quickly enhanced through computing power, algorithms, and storage capacity, these Geographical information Systems clearly were expert systems that needed considerable academic and technical education to be used. At the same time, data collection was clearly an agenda of the nation state and its administrative entities.

In the early 1990, first steps were taken in the direction of including lay users in GIS-routines

(Schoorman 2000; Elwood 2006) following considerable critique from social geographers and critical cartographers (Pickles 1995; Schoorman 2000). These first public participation GIS (PPGIS) allowed for the attachment of values and weights to specific layers of data in decision support systems. Here, however, the available data was still fixed, and the algorithms were probably beyond the comprehension of most lay participants.

During the first decade of the twenty-first century, several developments took place at the same time: the advent of usable and cheap Global Positioning Systems (GPS) and the end of disturbed GPS signals allowed for the development of lay mapping (variously dubbed neogeography, location-based media, or Volunteered Geographic Information (VGI, Goodchild 2007; Sui et al. 2013). At the same time, these GPS systems became standard in the now ubiquitous smart phones. Mapping was no longer in the hands of administrative entities but was increasingly organized by private companies like Google and ESRI or open-source based as in Open Street Map. The current landscape may be termed Geoinformation society and can be described through the availability of the following features (Strobl 2014; Harvey 2013; Thielmann et al. 2012):

- Universal positioning through various Global Navigation Satellite Systems such as GPS and a wide variety of receivers on humans and moving objects
- Personal sensors as a tool to integrate data via location and personal preferences
- Location-enabled apps that allow place-specific personalization of information
- Augmented reality that provides a additional visual information through a variety of devices
- A change of the traditional bird’s eye cartography towards individualized visualizations of space
- New interfaces that change human–computer interaction from keyboard/mouse interaction towards touch and gesture driven forms of interaction
- Personal and interpersonal devices linked to cloud services

This newer development can be categorized in three phases (Wilken 2018). In a first generation, these services needed an active registration of the users location (such as in the original Foursquare app). The second generation, then, involved passive location disclosure that automatically tracked the users' movements and linked this tracking to other content. Current applications, in a third phase now integrate location in all aspects of the business model, both in the interface as well as all algorithms, database population, and monetizing, as is the case with Uber (Wilken 2018, 26). This phase may be termed ubiquitous data capture. Location is the main integrator of all app processes here, and while it is becoming ubiquitous, the algorithms become increasingly opaque to the end user.

These – and probably more – developments over the coming years lead to new forms of communication, of the appropriation of space in both scientific and everyday settings, and consequently, to new forms and needs of learning.

Roles in Geomedia-Based Learning

Teaching and learning resources both theoretically and practically follow their availability as well as pedagogical thoughts. However, between these different ideas, specific differences can be detected in terms of aims, stakeholders supporting these approaches, and learning paradigms used (Gryl et al. 2014). Here, these approaches will be discussed under their title of (a) a technical perspective, (b) the perspective of Spatial Thinking, (c) the perspective of Spatial Citizenship, and (d) the perspective of Spatially Enabled Learning.

Depending on the technology and pedagogical approach, a variety of roles can be identified that link technology, GI professionals, and learners. Different from earlier thought, an increasing use of geoinformation in everyday communication leads to a widened classification of users in the professional GI domain. Consequently, these professional roles are (Fig. 1):

- Spatial information systems managers, who take care of the basic information-technology in terms of databases, technical ontologies, user interfaces, and other technical routines

- Spatial analysts who actively use the system from a scientific domain perspective, mainly producing analyses based on location, i.e., these are usually overlay, network and other algorithms developed in the spatial approach
- Spatial communication system managers who organizes mainly spatial visualization and communication tasks based on geoinformation
- And, in the case of education, didactical designers who have significant technological and pedagogical content knowledge (TPCK) to organize learning processes using geomedia

All these roles require significant education and training that cannot be acquired in secondary education and are therefore reserved as a aim of postsecondary education where a wide variety of respective courses is offered and theoretically founded in documents such as the GIS & T body of knowledge (diBiase et al. 2006; Wallentin et al. 2015).

Pedagogical Approaches in Geomedia-Based Learning

On the level of everyday users of geomedia, and therefore secondary school students as well, a very different set of roles is envisaged. These roles include a low level technician, a spatial thinker, a spatial citizen, and a spatially enabled learner (Gryl et al. 2014). This section follows the pedagogical arguments and gives information on exemplary topics and learning environments.

Technician: Enlarging the Geospatial Workforce

Actually, the technical argument and the argument of the enlargement of the technical workforce has been one of the first ideas that have inspired pedagogical engagement with geoinformation and Geographical Information Systems. This clearly is linked to a perceived bad image of the subject of geography in general education on part of geography educators, as well as early industry initiatives by software companies that for both economic as well as idealistic reasons wanted to make geoinformation, cartography, and spatial

Educational Resources, Geographical Information, Geomedia, and Learning, Fig. 1 Professional and general education roles in geomedia-based learning. (Based on Gryl and Jekel (2012), revised)

analysis available to secondary students (e.g., ESRI, Kerski 2003). Digital Geoinformation was seen as a tool to make the school subject more popular and in second line to provide the growing geospatial industry with a workforce of skilled workers.

Considering the state of the technology in the early 1990s, lots of energy in the classroom was spent on what today would be considered software training, providing software skills that

had a very short expiry dates as well as little conceptual foundation. In more general terms, it is rather questionable if general education should embark on software training at all. At the same time, the development of digital globes and later, the simplification of software and online application on handheld devices was much closer to the real-world experience of users who do no longer have to understand expert systems and full professional strength

software. Quite early, it was therefore noted that there was a need for “minimal GIS” (Marsh et al. 2007) in order to foster conceptual understanding instead of technical skills. Today, the discussion and praxis of GIS in a software training environment in secondary schools has widely subsided.

Spatial Thinker: Geomedia in Science Education

Spatial Thinking is neither new nor is it specific to the discipline of geography. Whenever organizing ourselves in space, humans do employ Spatial Thinking of one way or the other (Sinton et al. 2013). Quite a few disciplines are involved in secondary education when it comes to Spatial Thinking: maths, when looking into vector algebra; physics, e.g., concerning mechanics; geometry; and biology in a variety of scales from the double helix of the DNA to ecology (NRC 2006). It is this multiperspective view onto Spatial Thinking that allows the NRC (2006) to call for Spatial Thinking as a cross-cutting field of qualifications that should be widely implemented in secondary education:

Spatial Thinking must be recognized as a fundamental part of K-12 education and as an integrator and a facilitator for problem solving across the curriculum. [...] Our goal must be to foster a generation of students (1) who have the habit of mind of thinking spatially, (2) who can practice Spatial Thinking in an informed way, and (3) who adopt a critical stance to Spatial Thinking.

Basic Concepts

While the idea of Spatial Thinking in geography education was still originally inspired by the urge to bring GIS into the secondary education classroom, Spatial Thinking clearly was the first concept to do so with a general education background, and a wide array of geographers, psychologists, and learning theorists involved. It therefore pays dividends to take a closer look into the basic concepts employed and get these concepts related to their strengths and weaknesses.

The key to Spatial Thinking is a constructive amalgam of three elements: *concepts of space, tools of representation, and processes of reasoning*. It is the concept of space that makes Spatial Thinking a distinctive form of thinking. (NRC 2006, 12)

By *concepts of space*, authors of the Spatial Thinking approach mean various measures and dimensions within an absolute concept of space. These include, but are not limited to, relationships between units of measurement (meters, miles), different ways of calculating distance (for example, meters, time, travel costs), the dimensionality of spaces (two- vs. three-dimensional space), and the knowledge of coordinate systems. As linked to absolute space, these aspects may be mathematically calculated.

Concerning the term of *representation*, what the authors really mean is cartographical representation. This becomes clear through their dimensions of representation, namely the relationship between views (plan vs. three-dimensional visualizations, effects of projections, and principles of (carto-) graphic design (legibility and visual contrast). Again, all these forms of representation are geared towards a formalized representation of space within the rules of both traditional and modern (online-) cartography.

The notion of *spatial reasoning* is linked to analysis through spatial dimensions (distance, direction, and inclination). Reasoning here describes the extrapolation or interpolation of phenomena, the projection of (real or assumed) functional relationships describe through the dimensions of absolute space.

The spatial thinker therefore paradigmatically can be linked to the idea of the spatial approach, assuming that both natural phenomena as well as social phenomena can be described through spatial analysis. It therefore is a very useful approach for all phenomena that can be described as rule based, mainly in the sciences domain.

Exemplary Learning Environments

Water runoff and flooding. One of the areas that definitely may be explored using the Spatial Thinking approach are the relationships between morphology, precipitation, water runoff, and flooding. At the Z_GIS ideas lab, a learning environment has been built that consists (a) of a sand-pit for students to model their morphology, (b) a camera that allows for real time 3D-modelling of this morphology, and (c) the possibility to model precipitation and water runoff according to the

Educational Resources, Geographical Information, Geomedia, and Learning,

Fig. 2 Morphology, 3D-models, and runoff modelling. iDEAS-Lab, Salzburg, foto by C. Gruber

morphology. Questions that have been successfully explored with students include the velocity of water runoff in regulated versus meandering rivers. Students then could explain the correlation between the lower inclination of the meandering river and a slower runoff (Fig. 2).

Another topic that can be used as a typical Spatial Thinking exercise is the *modelling of noise pollution* as has been demonstrated by various authors (Staub 2014; Bette et al. 2014). Measurements can now be taken with smart phone apps and distance-decay models derived from students' measurements – including anomalies of the model according to surface, vegetation, and other determinants of the spread of noise. The learning environment therefore also allows for a critical reflection of model building and accuracy.

A third application of Spatial Thinking may be the *development of hypotheses* and the reasoning from spatial visualizations. This has been supported by the development of rather simple online platforms like Gapminder. These platforms allow learners to manipulate and visualize data and draw their conclusions, e.g., build hypotheses of correlations similar to visual analytics. Quite a few teaching materials have been developed for this endeavor (see Gapminder s.a, Jekel 2014). Recent empirical research (Jekel and Lehner

2017) has shown that these tools actually pre-structure hypothesis generation, and that some of the representation aspects of Spatial Thinking are especially noteworthy for the development of learning environments.

Reception and Critique

The learning to think spatially approach (NRC 2006) leant itself towards the popularization of geomedia in education in a variety of ways. It first underpinned a technology-oriented approach by a wider pedagogical aim that was rooted in science education (MaKinster et al. 2014). It was thus still keeping the industry interested, as in most early applications a broad range of technologies was involved. In addition, the Spatial Thinking approach also appealed to moderate constructivist pedagogies and problem-based learning, and therefore, empirical research (Lee and Bednarz 2009). The approach was used in a wide variety of learning environments, and it reintroduced the paradigm of the spatial approach in secondary education. As such, it found its way in many legal documents of secondary education such as the US National Geography Standards (National Council for Geographic Education 2012).

While the general idea of learning to think spatially was brilliant in providing a further

strengthening of science education in the subject of geography and beyond by explicating a specific way of thinking relevant across science disciplines, the same cannot be said for the humanities. As Gryl and Jekel (2012) argue based on Werlen (1993) and Lefbvre (1993), the spatial approach as underpinning the concept has little relevance in the humanities as everyday human decision-making is usually not based on data, spatial laws, and rational choice. The same is true for the analysis of the political arena, where power, resources, persuasion, beliefs, and communication are important dimensions of analysis. In other words, learning to think spatially may be used with great benefits in the sciences domain; it should, however, not be transferred to the humanities considering the specific ontologies of society and space.

Education for Spatial Citizenship: Geomedia in Humanities Education

Education for Spatial Citizenship starts its pedagogical endeavor from a completely different angle. It argues that geomedia – as has been discussed in the introduction – has become an ubiquitous and pervasive resource that changes our everyday appropriation of space. It therefore is about learning how to navigate the world in respect to the physical world, in respect to the meanings attached to physical objects and environments and in respect the power relations involved in the production of meanings of space.

Basic Concepts

As all three of these dimensions are inherently linked with geomedia in this day and age, general education therefore should take into account the competences needed in regard to these conditions of the appropriation of space. In their programmatic paper, Gryl and Jekel (2012) argue for three dimensions that should be characteristic of a spatial citizen:

- An (increasingly minor) set of technical skills that allows citizens to produce, interpret, and prosume geomedia. This includes orientation in physical space using geomedia, simple tasks of mapping and lay map generation, and an

understanding of commenting on other peoples' spatial representations via online geomedia environments.

- The ability to both reflect others' use of geomedia, as well as be reflexive regarding one's own use of applications that are based on geomedia; this includes being capable of deconstructing maps and spatial representations used in political decision-making, as well as reflexivity towards surveillance and control of the individual built into spatially aware applications.
- The ability to communicate and successfully participate in society using geomedia, using the power of maps to good effect within the borders of human and constitutional rights. This dimension supports an activist approach to education, with the idea to actively change societal relations to follow either individual or collective interests.

This general idea of Spatial Citizenship is therefore rooted in critical thought, and more specifically critical cartography/critical GIS (Harley 1989; Wood 1992; Schuurmann 2000). It is clearly denoting the social construction of maps and the power relations involved. However, Spatial Citizenship then goes on to make the power of maps available to secondary students. The focus is both on the analysis of societal relations as well as changing exactly these relations using geomedia.

Exemplary Learning Environments

Mapping migration histories: The aim of mapping migration histories with secondary students in Seattle (Elwood and Mitchell 2013; Gordon et al. 2016) was to raise awareness of “hidden places of history,” places that were missing in dominant discourses of local history. The students' mapping exercise therefore have been examples of counter mapping – a form of mapping that actively places maps at the center of an alternative discourse. While these mappings were not considered to be powerful maps in themselves, they empowered students from migration backgrounds to find places of remembrance of their own family's histories; they were able to reflect on the power relations that lead to the

inclusion or exclusion of specific histories; and they were able to competently argue with city officials on new places of remembrance in the city's official history. Consequently, Gordon et al. (2016) do not speak of the power of maps that helps students to support their own ideas but discuss the mapping process as an activity that supports the formation of the political subject.

Reflecting on spatial privacy and surveillance: The ubiquitous use of geomedia also allows for a new quality of surveillance and control of both goods and individuals. Tracking of persons, linked surveillance cameras, and geo-located uttering on social media lead to the fact that everyday geomedia users not only produce volunteered geoinformation but also un-volunteered geoinformation. Google street view and high resolution imagery are other intrusions into spatial privacy (Armstrong and Ruggles 2005). Early conceptions on tracking and privacy for secondary education have been provided by Stark (2014) and Hofmann et al. (2013) who both looked into the tracking possibilities provided by geomedia. Stark emphasized the two-pronged nature of spatial surveillance, helping pupils to understand the benefits (for example, for city planning or in case of alpine accidents) as well as the possibility to intrude others' private spheres. Most of these exercises nowadays are easily done with students private smart phones which at the same time are the major contributor to surveillance close to no-one really wants to miss out on.

Confronting the extreme right through geomedia use in education: With the emergence of a distinct turn to the right in western politics, digital maps came used by various groups came into an educational focus. Maps here were used to change public opinion, and in several cases, transport explicitly nationalist and inhumane content. Pokraka et al. (2016) first provided a model to deconstruct these maps with secondary school students, and Golser and Jekel (2017) provided a model based on current definitions of rightwing extremism to analyze these maps providing teachers and students with the relevant categories (Fig. 3).

Another approach was suggested by Jekel et al. (2017) through mapping the physical symbols of NeoNazi movements in physical space of the city

under an initiative termed *#notmysymbol*. Mapping was organized through a combination of geolocated images of these symbols and the hashtag of *#notmysymbol* on Instagram. The initiative followed several aims, online mapping usable by stakeholders of the state, and law being the superficial starting point. Students were also asked to reflect on their mapping and interpretation practices as well as transfer the analytical capabilities developed to everyday media.

Organizing the city and the state in primary education: In an analog mapping experiment by Gryl (2015), children aged between 8 and 11 years were given the task to draw their functional fantasy world collaboratively (cf. Odenbach 2011) on a floor-covering paper with a few predefined imagined continents. They added natural conditions (including terraforming), settlements, infrastructure, and economy. They split up in groups that were each focusing on one continent or country each. The experiment resulted in a geopolitical game, starting with border controls when a child wanted to collect crayons lying on another part of the world, and ending with arms race along the borders of neighboring groups. So, beside creative and clever outcomes of functional world economies within the lollipop harvesting business, an anarchic and/or violent tendency appeared as well.

Reception and Critique

The approach of education for Spatial Citizenship has been expanded in several directions. One has been to link Spatial Citizenship and critical thinking (Carlos and Gryl 2013; Gordon et al. 2016). Another one has explored the implications of specific use gaps between genders and the benefits the Spatial Citizenship approach can draw from feminist and queer perspectives (De Luca et al. 2015; Ferber et al. 2016). In addition, the Spatial Citizenship approach has also informed participatory design initiatives based on youth mapping projects of the city (Hennig and Vogler 2016).

In early versions of the concept, both the conceptualization of citizenship as well as the radical constructivist aspect of the Spatial Citizenship approach were questioned, noting that the basic conception was easily misunderstood as fostering

Educational Resources, Geographical Information, Geomedia, and Learning, Fig. 3 Results of the collaborative mapping process, city of Salzburg (Austria) displayed on a mapping application prototype: (1) delivering a map interface including all collected symbols, (2) highlighting the selected post, (3) showing the photo of the

selected post uploaded to Instagram, and (4) delivering the location, the direct link to the original Instagram post and embedding the comment added to the Instagram post by the uploading user (screenshot from the mapping application prototype)

a very conservative aspect of administratively bounded citizenship, and even fostering nationalist tendencies. While Gryl and Jekel (2012) already based their original work on the idea of an actualized citizenship by Bennett et al. (2009), further clarifications on useful concepts of citizenship have been provided by Bednarz and Bednarz (2015), Jekel et al. (2015), as well as Gryl et al. (2017). The latter contribution also discusses a possible normative background in some more detail. Gordon et al. (2016) in addition hinted at a wider conception in their work – rejecting the notion of the powerful map user as the aim of Spatial Citizenship education and instead arguing for the contribution of Online and VGI mapping strategies being a contribution to the formation of the political subject. This can be considered to be an idea to be followed in education initiatives in future.

Another recent development and widening of the Spatial Citizenship approach has been the connection towards innovation and innovativeness (Jekel et al. 2015; Scharf et al. 2016). Here, the role of geomedia in reinventing the world is discussed, both in the technical as well as in the social sphere, and empirical research into support systems has just begun (Jekel and Lehner 2017).

The above examples of learning environments, however, show that the basic ideas of the spatial citizen approach – a minimal set of technical competences, the ability to reflect on individual, collective, and economic geomedia use, and the ability to communicate to a wider society can actually be reached with the technologies available. The approach of Spatial Citizenship education therefore is the humanities equivalent of the Spatial Thinking approach for science education.

Spatially Enabled Learner: Geomedia as an Integrated Education Platform

Among others, Thielmann et al. (2012) and Vogler et al. (2012, 205) state that we live in a “spatially enabled society”: Spatial representations are omnipresent and provide information layers for everyday information and decision-making. While the availability of mobile devices, the mobile web, social web applications, and globalization outcomes in general seem to support de-location in everyday understanding and action (Gryl et al. 2017), the combination of these aspects with geolocation technologies leads to a “renaissance of place” (Schroll et al. 2007, 26, transl.) that utilizes the information that is linked to a geographical reference. Information for many purposes in life are georeferenced, for instance, information on everyday transportation, consumption, and leisure activities.

Spatially Enabled Learning is an approach that utilizes the omnipresence of (digital) maps in order to improve learning while taking into account the communicative and collaborative potential of the current geoweb, i.e., the ubiquitous usability and continuous reproduction of geomedia via handheld devices. Inspired by the variety of content added with georeferences in everyday life enabled by geolocation technologies, from political issues (e.g., The Hoax Map) to sustainable consumption (e.g., Mundraub), Vogler et al. (2012) developed this term by identifying learning with spatial representations as added value for several subjects beyond classical geographical topics. Typical learning examples within this approach are learning about places mentioned in novels, about statistics concerning countries and regions, and about cartographic narrations on product chains.

Spatially Enabled Learning environments may “bridge the gap between everyday social geocommunication and collaborative learning environments in education” (Vogler et al. 2012, 209). The approach “aims at the integration of communication and geo-technological tools into a state-of-the-art (e-)learning framework” (Vogler et al. 2012, 205). This includes that learning content is not only spatialized/georeferenced by teachers but also by learners, who communicate

themselves. For this purpose, in accordance with Vogler et al. (2012), it is suggested to use simple representations – online mapping tools such as used in the Spatial Citizenship approach, supported by everyday technology (mobile devices).

In sum, “Spatially Enabled Learning makes use of web-based spatial representations to support interaction, communication and document learning outcomes in educational contexts by connecting complex learning content to a spatial dimension. This can be achieved by contextualisation, by cartographic support of arguments in communication processes or simply as a spatialized portfolio that may be either individual or collective or both.” (Vogler et al. 2012, 206).

Basic Concepts

Spatially Enabled Learning is a concept primarily designed for providing an added value to learning. In contrast to the Spatial Citizenship approach, the main aim is rather individual and collective gaining of insights more than public communication and convincing others. However, Spatially Enabled Learning is a valuable basis for understanding the spatial aspects problems and a starting point for acting as a spatial citizen. Furthermore, competences developed as spatially enabled learners are fruitful for societal participation as well. The approach bases on two main theoretical references: (1) relational spaces and (2) dual coding.

- (1) Spatially Enabled Learning clearly bases on the idea of the attachment of meaning to physical matter by communication through spatial representations. At this, the meaning is represented by learning content that can be georeferenced. Mainly, this approach refers to representations of geographical spaces (for instance, a map of places that shows indicators/results of climate change, or fictional events in novels taking place in existing cities), but apart from this, all representations that use spatial relations, including fictional landscapes (e.g., map in the Lord of the Rings), are useable. The main aspect is that meaning/content, and therefore spaces are regarded as socially constructed.

(2) Maps address the dual coding functionality (Paivio 1990) through a combination of pictorial (maps as picture) and symbolic elements (maps as text) that target at different modes of information procession in the learners' reception, as described in mapping theory (Wood 1993). The usage of two channels at the same time refers to the added value for memory and learning that pedagogical psychology notices when text and pictures are combined (multimedia principle, Weidenmann 2006; Schnotz 1995). On the web, mashups lead to the combination of several sources of information and modes of representation, so that dual coding functionalities are nowadays transformed into multicoding. Enemark and Rajabifard (2011) describe the link between analog codes (learning contents) and symbolic codes (spatial representations) with a positive effect on the memory and understanding of complex information as another aspect of maps that might run under the dual coding label.

Furthermore, the combination of information with location – a spatial contextualization – supports learning as well as methods in mnemonic training (Krämer and Walter 2006). Similarly, map information supports the understanding of complex, nonlinear relations (Wood 1993). Apart from that, current spatial representations on the web combine the duality between individual and social construction of meaning.

Moreover, Spatially Enabled Learning refers to an inclusive component: The code system of mapping that uses pictorial elements, and, particularly in simple web mapping, a quite consistent and broadly used design, supports communication beyond cultural, language, and literacy barriers (Hall and Jones 2012). “Communicating via spatial representations may bridge learning contents beyond learners' verbal skills and (dis)advantages.” (Vogler et al. 2012, 206). Therefore, Vogler et al. (2012) closely link this approach to social geocommunication which means the communication with the help of spatial representations that may be utilized for learning purposes, both concerning information and hypothesis

construction for the single learner, and production of content and collocation for learning teams.

Exemplary Learning Environments

The Spatially Enabled Learning approach is useable for all learning content that can be visualized in spatial representations, which means all georeferenced content with potential interest for gaining insights in formal and informal learning processes.

In the project “Tripping Stones in Landau – histories of people,” students of a middle school (Integrierte Gesamtschule Landau) mapped tripping stones (Stolpersteine) that shall keep up the remembrance of the victims of the Holocaust in their home town Landau (Pfalz, Germany) using Google Earth. This example, conducted in collaboration with one of the authors of this paper, is situated in the field of history education, as the students searched in the municipal archive for information about these people. While doing so, they learnt about the enormous crime that made these people victims but also about their lives they had before. These everyday historical narrations give the partly persons back their identities and faces. Students located the tripping stones, placed them on a map, and added the biographic information they had investigated. The map was published on the school website. This act of geovisualization is an example of Spatially Enabled Learning, as different modes of representation were addressed and a layer of history was put on the town. This layer illustrates that the victims of the regime once have been omnipresent and fully integrated into the town – their presence and the knowledge of their extinction gives another insight into the terrifying dimensions of the Holocaust. Similar learning environments have been developed by Schellenbacher (2017) as well as Wöhs et al. (2018 in print) (Fig. 4).

Mapping fair trade facilities: Vogler et al. (2015) conducted a mapping project named Youth Map 5020, which contained, among others, digital mapping of fair trade shops in the students' home village. Students did not only practice the method of mapping nor did they not only draw societal attention to the concept of fair trade, but they also built a profound basis to learn about fair

Educational Resources, Geographical Information, Geomedia, and Learning, Fig. 4 Students' mapping of tripping stones in Landau – geovisualization in history education, Integrierte Gesamtschule Landau

trade (definition, different labels, categorization) and to gain more insight (distribution of shops in correlation with location factors) (Fig. 5).

Platforms that could be used for Spatially Enabled Learning still need more development, including partnerships with the industry, and should combine functionalities of traditional learning management systems with cloud-based mapping and communication tools to contextualize most learning materials, learning outputs, and additional information. The outcome would be a spatialized portfolio that could be both individualized and also collective in terms of classroom practice, showing not only locations of learning, blind corners but also spatial concentrations of individual knowledge production.

Conclusion and Outlook

As it has become clear in the discussion of the four approaches above, they differ significantly in terms of aims, stakeholders, learning theories

and epistemology, concepts of space, pedagogical approaches, and the roles and capabilities learners should acquire. With the advisable exception of a purely technical perspective based on software learning, all approaches can be seen as useful structural components in secondary education (Table 1).

Two dimensions particularly link into each other: learning theories and concepts of space used. Spatial thinkers derive their insight from using absolute space and spatial laws, while spatial citizens are based on the assumption of socially constructed, relational space. It has been argued that this differentiation is responsible for their rootedness in the sciences and humanities domain, although it can also be linked to the concepts to moderate vs. radical constructivist perspectives of learning. This can be traced to the respective pedagogical approach used. In the sciences, and therefore Spatial Thinking domain, model- and problem-based learning are used, while for the education of spatial citizens, inquiry based-learning,

Educational Resources, Geographical Information, Geomedia, and Learning, Fig. 5 Susan straight's' The American Experience in 737 novels, story map. <https://storymaps.esri.com/stories/2017/737-novels/index.html>.

The story map here looks into the local embeddedness and spatial context of literature – a model for learning materials in general

Educational Resources, Geographical Information, Geomedia, and Learning, Table 1 General outline of geomedia-based learning approaches

	Technical perspective	Spatial Thinking	Spatial Citizenship	Spatially Enabled Learning
Aims	Workforce development	Science education	Citizenship education	General learning
Stakeholders	Industry	MINT-subjects	Humanities	General pedagogy
Learning theory	Behaviorism	Moderate constructivism	Constructivism	Constructivism
Concepts of space	Absolute	Absolute	Relational	Absolute and relational
Pedagogical approaches (examples)	Software learning	Model-based learning Problem-based learning	Inquiry-based learning, project based learning, activist education	Locational games, spatial portfolios
Role of geomedia/ geoinformation	Technical system, software	Organizing phenomena in absolute space	Tool for reflection and communication through power relations	Organizing and supporting general learning spatially
Roles of learner	Technical user	Spatial analysis, technical research and development	Activism and participation, political subject in society	Spatially organized member of society
Authors	Kerski (2003)	NRC (2006)	Gryl and Jekel (2012)	Vogler et al. (2012)

project-based learning, and activist education are more common.

It is suggested that Spatially Enabled Learning will become the norm across subjects, just as

Google or Wikipedia nowadays also provide the possibility to organize much of their information spatially. The technology is available. Currently, the providers of learning management systems,

however, have not jumped the train, while software companies like ESRI would easily provide the necessary solutions in terms of online mapping and communication.

In future, expect many learning processes to be spatially enabled following the everyday localization of information, services, and activities with the help of digital devices and geolocation technology. Within Spatially Enabled Learning environments for general education, the concepts of Spatial Thinking for science education and Spatial Citizenship for citizenship/humanities education will perpetually apply as inevitable aims of an education that utilizes geoinformation. They can be considered a reasonable and sustainable basis for geomedia-based education across subjects in the respective domains.

Hypermedia in a Nutshell: Historical Landmarks

Hypermedia, in short, relates to a *new kind of resource* that links several kinds of documents (texts, images, sounds), allowing easy nonlinear navigation through the material. But this is only one view of a more complex matter. In what follows, some historical indications shall be given, and then the case of hypermedia for education will be analyzed.

It is generally assumed that the idea of hypertext dates back from Vannevar Bush, at the end of World War II. In his seminal paper (Bush 1945), he presents the new perspectives offered to mankind by technology and imagines a future using the new potentialities of machines for intellectual tasks: computation, manipulation of ideas, selection of the right data, etc. Stressing the fact that the ability of associating is at the core of the human minds, he describes a visionary artifact (the “memex”), using technology known at that time, that would allow, with microfilms, dry photography, etc. to perform “associative indexing” between documents, tying together permanently

different items. This would allow users to form and to memorize trails of associated items.

It is also generally known that the implementation of such an idea is largely due to two other thinkers: Doug Engelbart, pursuing a lifelong quest of “augmenting” the human mind, designed a system called NLS/Augment (Engelbart and English 1968). Ted Nelson, who is credited with the invention of the term “hypertext” (Conklin 1987), developed a system named Xanadu that implemented clever ideas such as the difference between “content links” and “transclusions” (“connections between things which are *the same*”) (Nelson 1999).

Hypertext and hypermedia were therefore actually born before the invention of the World Wide Web, at the end of the 1980s. After that date, links did spread everywhere, and the word “navigation” enriched its spectrum of meaning with a travel on an ocean of data. Quite interestingly, the denomination of the software allowing this navigation is “browser,” which comes from a whole different semantic field.

Ted Nelson remarked in his 1999 text that what the Web implemented was a small part only of the potentialities of hypertext: “The World Wide Web was not what we were working toward, it was what we were trying to *prevent* [...] Its one-way breaking links glorified and fetishized as ‘websites’ those very hierarchical directories from which we sought to free users, and discarded the ideas of stable publishing, annotation, two-way connection and trackable change.”

The undeniable reality of that time has however changed a lot with the apparition of systems dynamically generating content and able to adapt to the user’s profile, as exemplify today search engines.

Hypermedia in Education

In education, the interest for hypertext and later for hypermedia surged in the 1980s. Basically, what a hypermedia offers is the opportunity to follow a path on a graph of situations or resources, each node giving access to a set of another ones (those implemented by designers of the system).

The idea of hypermedia now seems very natural, on account of the enormous dissemination of the *World Wide Web*: nowadays, nearly everyone assumes, when seeing a blue and underscored text on a screen that a *link* is hiding behind it and that, by clicking on it, one should be transported to some other document, which should have a logical relation with what the text indicates. The same is true also with clickable images.

This is in a way very similar to computer-assisted learning, but the major difference stems from the fact that the transition between nodes is not at the initiative of the program but depends on the user's choice. Such an environment is therefore supposed to be in accordance with the principles of constructivist learning. Many research works have been done on the effects of using hypermedia as a way to explore and to learn a domain, the risks of disorientation in the cyberspace being pointed very early.

In a review, Bruillard and De La Passardière (1994) observed that, in education, hypermedia may act either as cognitive tools for discovery learning, allowing learners to browse and restructure information (in the line of micro-worlds popularized by researchers like S. Papert around the LOGO language (there is a great intellectual continuity between LOGO and the modern systems like Scratch aiming at facilitating programming by young children.), or as tutors (but then they encounter the classical and thorny problems of maintaining a good cognitive model of the learners).

With the spread of the Web, everything offering a hypermedia side, a new interest toward the use of adaptive hypermedia surged in the 1990s. In a later review, Brusilovsky (1996) presented different forms of adapting the Web to users' profiles (text shown, direct guidance, adaptive sorting, hiding and annotation of links, multimedia presentation, map, etc.). His paper stresses the fact that it is promising to let users adapt the presentation and take into account those changes and forecasts the importance of the Web.

In October 2017, a search on *Google Scholar* with “hypermedia” and “education” as keywords showed that the number of references has known a steady yearly growth (from 600 in 1990 to 7600 in 2015). When hypermedia was replaced by “adaptive hypermedia,” the fraction of results, which was below 1% in 1990, grew to more than 10% after 2003. This confirms the rise of a new interest in adaptive environments, whatever be the principles underlying them.

Things keep on moving. Computer tools have now become a commonplace. They help humans

(and also constrain them) in every activity they lead. Being banalized, hypermedia has lost its innovative side. But it lingers on. Modern systems allow everyone to propose new associations in large data repositories and to offer users opportunities of discovery. Hypertext is at the core of the matter, allowing to associate strings of text with other texts that may point toward multimedia resources. Its adaptiveness now relies on new algorithms exploiting “big data” and creating profiles for users according to the traces they left, based on algorithms comparing individual profiles with those of a mass of others. However, if this approach now seems to work quite well in marketing, for adjusting commercial platforms, it is far more difficult to adapt it to education.

Introduction

Global dissemination of information and communication technologies (ICTs) was supposed to lead to development and reinforcement of global democracy. However, despite the global dissemination of ICTs, realization of equitable enjoyment of its benefit is still seen problematic. Instead of promoting democratic values through the dissemination of ICTs, the digital divide has been reported emerging and widening (Revenaugh 2000).

Accordingly, this article explains how “educational support on computing and informatics for disadvantaged groups” has been understood and investigated as an academic topic in pursuit of promotion and improvement on empowerment activities in this field exercised in real societies. The topic, rooted on a context of research on computing and informatics education among citizens, represents a social concern to be addressed for realizing a social circumstance called “knowledge society” allowing every individual to

equitably participate in as an active member playing a role of knowledge creation. Despite emphasis of academic research put upon computing education mainly in schools, supporting broader range of individuals in learning and enjoying computing and informatics has been grappled with in terms of both social activity and academic research, from a viewpoint of civil empowerment (Saito 2017). Recent social transformation caused by the emergence of knowledge society, which was enabled by a massive use of digital technology in society, enlarged significance of the topic regarding a practical concern linked to actual practices on computing and informatics education among a nonformal learning sphere. A basic concern of the researches on the topic is generally put upon how individuals’ well-being can be improved through the educational support. Concerning disadvantaged groups in current societies, their disadvantage, which is linked to social, economical, and political participation, as the lack of capacity to utilize potentials of computing for their own knowledge creation, is supposed to get larger today, which means they are at risk of being excluded from freedom of social participation. Therefore to support disadvantaged groups’, social participation through helping them in learning computing and informatics becomes inevitably a central mission which calls for various attempts in this field.

Background

Shared Recognition on the Digital Divide and Demand for Social Inclusion

Actual engagement on the topic of “educational support on computing and informatics for disadvantaged groups” started practically and theoretically motivated by a recognition shared by the study on the digital divide that approaching the digital divide should be based on the conception of empowerment. With regard to discussion on how to address the digital divide, current focus of the discussion has shifted from achieving equal access to ICTs with providing physical infrastructures toward delivering equitable opportunities for individuals to enjoy substantial improvement of

well-being through empowerment on technology use (Revenaugh 2000). This shift of discussion reflects the fact that just having “access” to ICTs is not sufficient for fulfilling various life demands which well-being of individuals comprises. Empirical researches on the digital divide have revealed the attributes and background factors that may affect individuals’ disparity not only in access but also in use of ICTs, which are, namely, race, ethnicity, gender, class, educational background, and other factors relating to the socioeconomic situations (e.g., Kvasny 2006). These attributes and factors commonly reflect social, economical, cultural, and historical circumstances of the society, which may form social circumstances inviting the disparity between the rich and the poor among citizens.

Results of prior research have brought about the shared recognition that approaching the digital divide should be based on the conception of empowerment. The empowerment in this context is directed toward fostering human capacities for living well through making good use of ICTs (e.g., Gigler 2011). The conception of empowerment as a basis for tackling the digital divide can be applied to the situation not only in developing countries but also in developed countries, since it is common for both of the countries to have social structures reproducing socially disadvantaged groups at risk of being excluded from informatized situation of society based on digital technologies. In terms of the empowerment for such members in society, the problem of digital divide can be understood intrinsically as a subset of so-called social exclusion, which is asking for promotion of equitable opportunities for digital participations (Wei and Hindman 2011). This means it is crucial to construct a blueprint of social inclusion into informatized situation of society under the circumstance of the globalized digital divide.

Indirectness Between ICTs and Well-Being as a Target for ICT4D

Findings of the study on information and communication technologies for development (ICT4D) also gave important knowledge toward the research on the topic of “educational support on computing and informatics for disadvantaged

groups.” Many of the literatures on ICT4D insist on the indirectness between ICTs as technological input and enhancement of the residents’ well-being as its output. Through the research on ICT development for rural communities in Bolivia, Gigler (2011) emphasized that no direct relations had been found between improved ICT access and enhanced socioeconomic development. In addition, using the notion of “catalyst,” Gigler argued the significance of “intermediary organizations” in converting ICT access into “meaningful use” of ICTs through educational support for the rural poor citizens. With the model of the ICT4D value chain, Heeks (2010) also argued the indirect relationship between ICT infrastructure and development impacts, which indicated the ICT access should be seen as merely a “starting point in understanding ICT’s contribution to development” (Heeks 2010).

The problem of the indirectness between ICT access and enhancement of residents’ well-being is supposed to be common toward the developed countries where ICT diffusion has mostly been completed. This indirectness is basically affected by the social structure reflecting inequality and inequity in obtaining learning opportunity of computing and informatics, which is seen not only in developing countries but also in developed countries (e.g., Kvasny 2006). Though the state of basic literacy is generally better in developed countries, the distribution of learning opportunities to convert ICT access into meaningful use of ICTs is still left to be insufficient.

Furthermore, the research on “educational support on computing and informatics for disadvantaged groups” is basically asking about the roles of computing and informatics education on the disadvantaged citizens’ empowerment in knowledge society. The preceding arguments (Hromkovic and Steffen 2011) have shown the roles of such education in introducing fundamental concepts of computing and informatics and in expanding human capacities necessary to utilize ICTs effectively for various purposes. The arguments also have reported that expanding such capacities enabled people to produce systematic ways of problem-solving with ICTs and to create representations reflecting their own ideas. The

role in expanding career choice with the enhancement of computing skills has also been discussed in some literatures (e.g., Hromkovic and Steffen 2011). There is, in addition, an argument which illustrates the educational role in promoting democratic participation, being considered as a basis of public education, through encouraging creating programs to contribute to others in the society (Schulte 2013).

However, the role of computing and informatics education hasn't been investigated and discussed adequately yet, especially in terms of empowering disadvantaged groups living in informatized situation of society emerging in the developed countries. It is believed that such investigation and discussion will add an alternative view of computing and informatics education's contribution toward the realization of digital equity.

A Case of Field Research: Educational Support on Computing and Informatics in a Group Helping Disadvantaged Young People's Social Participation

The topic of "educational support on computing and informatics for disadvantaged groups" can be understood better with a report of a case study conducted in a real empowerment activity. As an instance of such a report of the case study, Saito (2017) reported outcomes of a research conducted in a group, placed in a mid-sized city in Japan, which was organized to help social participation of disadvantaged youths. The research was conducted in pursuit of the research question as follows:

- What kind of possibility and limitation can be found in educational support on computing and informatics for socially disadvantaged youths in developed countries as a means of empowerment and social inclusion?

In the following parts, the outline of the research and reported findings presented in the article of Saito (2017) will be introduced to show how the topic may be researched and what

kind of outcomes may be obtained in such a research.

Research Question and Methodologies

According to the article, the purpose of the research is set to advance understanding of the significance of promoting learning opportunities of computing and informatics in terms of civil empowerment and social inclusion. Consequently, the research methodologies are explained as follows; to explore the research question, the author of the article joined a group's activity to help rehabilitation and social participation of the pupils and students with school absenteeism and the youths who had experienced socially withdrawal. The group was placed in a mid-sized provincial city in Japan. The group's size had varied during the research period; however, there were around five to ten young people with two to five staff members including part-time supporters. The author acted as a part-time member mainly to support such youths in getting familiar with computing and in learning something about computing and informatics. As a data collection, the author had made a series of text descriptions with some pictures and movies in the field that the author thought as field notes, noting events and occurrences, dialogues with group's participants, findings and interpretations, and reflections on every session during the research period. The data were analyzed into important themes and issues in accordance with the research question. This process was supplemented with further observations and dialogues in the field.

As described in the article, the research was to be conducted in May 2015, after a period of pilot study in the same field from December 2013 to January 2014. The article was published based on the findings of the analysis of the field notes taken from May 2015 to March 2017. During the period, the author and the young people in the group had been involved in learning introductions of computing and informatics with several practices, such as making games, teaching elderly people programming with Scratch, and constructing a programmable robot called "MugBot" (it is a non-proprietary open-source social robot originally

designed by Koike Laboratory in Tokyo Metropolitan University. <http://www.mugbot.com>).

The research followed the basic conceptions of action research as a participatory research methodology. Action research is explained as an approach “that enables people to find effective solutions to problems they confront in their everyday lives” (Stringer 2013) by collaborative commitment toward real social problems for a group of people that are relevant to the problems. In this methodology, the researcher is not merely an objective observer but a member who actively participate in the process of problem-solving. Moreover, the research process is interpreted as a process seeking for positive social change based on democratic values. The conception of action research was suitable for the research in pursuit for the shown research question, which called for practical engagement in an educational support project practiced in a real context of a developed country.

The Reported Findings of the Research

While joining the group’s activity, the author of the article had met certain amount of young people who were at various ranges of the ages (from elementary pupils to late 20s). Among the members the author had built a continuous relationship with some young people who were supported in the group for their rehabilitations. They were all the age of late 20s who had experienced the status of social withdrawal in years past and hadn’t have any opportunity of regular employment.

Based on the reflection and interpretation of the involvement with them, which had been noted in the field notes and other visual materials, the author reported in the article these suggestions shown below relating to the possibility of educational support on computing and informatics.

- With some triggers (e.g., suggestions on the joy of making games with programming, the way of obtaining teaching materials and other useful information in the web, and the annual event on Scratch programming) brought by the author, the young people got interested in using computers in more creative ways and autonomously engaged in learning computing.

- The young people were also motivated to learn introductory part of informatics and succeeded in finding the joy of learning it.

During the period that the young people were learning and practicing computing and informatics in the group, they enjoyed the chances to communicate with others (e.g., support staffs, other young participants, neighboring residents participated as volunteer supporter, and the pupils and students of the schools around) for their capacities of computing and informatics.

For instance, the author had noted in the field notes the circumstance in which the group’s members had decided to engage in constructing MugBot. According to the article, one of the main factors which driven the members to engage in constructing MugBot was supposed to be intellectual and emotional stimulation they obtained from a social event on Scratch programming held annually. They had been informed of the holding of the event from the author and had decided to attend it by their own decision, which described how the members’ emerging interests into creative aspects of computing had involved them into learning computing.

After that, the young people had begun to construct a unit of MugBot and kept their effort to complete all of the process of construction. Then they finally succeeded in completing the construction and controlling all of the basic functions (blinking eyes of LED, voicing given text data, and moving its head according to given programs) 3 months later from the beginning of the construction. While they were engaged in it, they supposed to learn controlling devices with programs and had experienced constructing an example of network system, which requires basic understanding of the Internet Protocol, merely with a textbook and other resources they found themselves. Very occasionally, the author of the article gave advices when they seemed to get into difficulties that might be beyond their capacities.

Moreover, their capacities of computing and informatics had become a cause of generating new communication with others visited their working space. For instance, when the group accepted some students of a junior high school

located near the group's space for the students' work experience program in the school, one of the young people had autonomously attempted to introduce making programs with Scratch toward the students. To the author's eyes, the time the student had spent for the work experience program seemed to become more meaningful and more pleasurable for it.

The author of the article also found these suggestions, as a result of reflection on the field notes, concerning limitations of educational support on computing and informatics.

- The young people's expanded capacities of computing and informatics didn't seem to expand obviously their motivation for making use of such capacities for their social participation to improve their personal situation in the surrounding society.
- Their motivation for making use of such capacities to improve circumstances of the community they belonged to also didn't manifest itself in their behavior.
- It seemed difficult for the group members (including the support staffs) to convert efficiently such capacities they had made into the group's competence.

With regard to the first and the second points, the author of the article faced the young people's strong refusal on engaging in the activity that requires being social. Together with that, the author reported "social" nature of programming, which means creating programs that can afford someone a certain level of convenience, as it inevitably requires consideration on others' convenience.

The incident in the field on which the author's consideration grounded was that one of the young people showed negative attitude toward the author's offer of creating a program based on her/his own or the group's needs of computing. The young people were quite positive when she/he had learned and reproduced programs according to some situation settings given by the textbooks. In addition, the young people seemed to have enjoyed learning an introductory level of

informatics with making programs according to the instruction in the textbooks. However, the young people had consistently expressed his indifference to create something which could be a solution for "real problems" concerning her/his personal or the group's daily activities making use of his capacity of computing.

The third point had related to the limitation of the members' participation in the educational support on computing and informatics. The group was mainly managed by two core staffs, who were the manager and the co-manager of the group, with the help of several volunteer staffs (one of the young people had changed her/his position in the group from a supported member toward a volunteer staff during the research period. She/he had been virtually supported in her/his social participation while working as a volunteer staff). In the author's view, they had had a shortage in staffs for the amount of their tasks, which made it difficult to involve themselves into the practice of computing and informatics as much as they could develop their own educational support programs by themselves.

The author of the article reported that he and the staffs had provided various occasions for the young people to encounter the practice of computing, mainly with Scratch programming as an introduction. And the author also noted that many of them actually seemed to be interested in practicing computing. However, the membership of the young people had not been stable because their participation in the group was basically left to their own circumstances, which were sometimes too complicated socially and personally to keep attending the practice.

Suggestions on the Educational Support Based on the Field Research

The Possibilities on the Educational Support Found on the Field Research

Based on the findings of the research conducted on the group supporting disadvantaged young people, the author of the article of Saito (2017) presented suggestions regarding the possibilities

and limitation on educational support on computing and informatics for such young people, in accordance with the research question shown above. The suggestions on the possibilities are as follows:

1. Such support can expand the mode of disadvantaged young people's daily use of ICT facilities.
2. It also can derive their desire for personal challenges of autonomous expansion of their computing capacities.
3. It can enlarge the young people's communication opportunities with others around.

According to the article, the possibilities found on the field research can be illustrated by the three suggestions shown above. The suggestion one tells about the expansion of the daily use of ICTs happened on the young people who joined the educational support. That is, the young people in the observed group had successfully learned to enjoy utilizing ICT facilities in more creative ways with programming, whereas they at first had very limited idea to utilize them because of their limited learning opportunity for the personal and social circumstances. The suggestion 2 shows young people's autonomy in expanding their computing capacities. This suggestion explains a possibility of the educational support to promote the autonomous behavior in learning computing among the young people. Actually, such autonomous behavior was reported in the article, which had commonly been observed among the young people's usual practices during the research period. The suggestion 3 describes an aspect of communication expansion brought about among the young people through participating in the educational support. As the author in the article reported, such communication opportunities were observed among the young people and also in the relationship with the people surrounding them, such as the staff members, volunteer supporters, visiting residents living nearby, and so forth, which had occurred in the context of computing practices.

Limitation on the Educational Support Found on the Field Research

The author of the article also presented the suggestions obtained regarding limitation of the educational support. According to the article, the limitation is classified as follows:

1. The educational support cannot turn disadvantaged youths' expanded capacities of computing directly into the ideas of applying it toward real problem-solving activities in social situations.
2. It also cannot enhance the youths' motivation for utilizing their computing capacities into strengthening their connections with societies around.
3. It cannot function without continuous help of volunteer supporters who have computing capacities and are ready for work with practitioners in the field.

The suggestions on limitation represent the problems regarding the educational support which should be solved in terms of sustainable empowerment for disadvantaged young people's social participation. The suggestion 1 refers to the limitation on conversion on acquired skills and knowledge into the capacity to solve social problems regardless of its scales. This problem is supposed to relate to difficulties with attracting the young people's interest in problem-solving in the real world. In the article it is reported that the young people had consistently shown quite reserved attitudes to engage in solving problems relating to the group's activities utilizing their computing capacities. The suggestion 2 focuses on the limitation on involvement of the young people with social relationships. The research outcome suggested the educational support had very limited influence on building the young people's motivation to make use of their expanded computing capacity to find and get involved in new social relationships available to them. For the young people reported in the article, strengthening of the connections with societies in this term had potentially contained seeking jobs, attempting to learn in higher education, creating the group's

new activity to contribute toward neighboring communities, and so force. According to the article, in the research period, any obvious incidents relating to these hadn't been observed. The suggestion 3 describes the limitation on sustaining the educational support only with the group members' effort. Planning and running the educational support requires expertise in computing and informatics and also the knowledge and skills on pedagogy in computing and informatics, to some extent. In the reported research, the author participated into the group's activity as a volunteer supporter and collaborated with the group stuffs to realize the educational support. However, as far as the reported research period, most part of the educational support in the group had maintained mainly with the author's participation.

Conclusion

The suggestions obtained from the research reported in Saito (2017) lead to two conclusions. The first conclusion is that premising collaboration of the practitioners of both computing and social participation support backgrounds, educational support on computing and informatics for disadvantaged young people in developed country has a certain potential of expanding their choice of "meaningful use" of ICTs, which is used following Gigler's (2011) viewpoint, with deriving autonomous participation in computing practices. This conclusion is consistent with the recent tendency of digital divide research which emphasizes the gap of "meaningful use" rather than "physical access" as a key factor of approaching inequitable circumstances of ICT use (e.g., Wei and Hindman 2011). Moreover, this conclusion corresponds with an ICT4D's evaluation framework, the "Choice Framework" proposed by Kleine (2010), which argues the significance of small case development studies on ICTs' role of expanding freedom of residents' choice as empowerment (Heeks 2010).

The second conclusion is that the educational support cannot be the solo factor to encourage them in their social participation through

utilizing their computing capacities. It is supposed that there will be a limitation within such educational support in terms of empowerment for social participation if computing and informatics are to be taught and learned merely as a value-free decontextualized knowledge by the learners. In other words, potential of the educational support to overcome the "indirectness" between ICT access and enhancement of residents' well-being should be understood restrictedly for the present state of the research in the field. This result is consistent with the indication made by Gigler (2011) that "improving the access to resources for the poor, for instance providing access to girls' education or access to ICTs only represents a potential for enhancing their capabilities and thus does not automatically have to lead to positive outcomes on empowerment."

Nevertheless, this does not mean educational support on computing and informatics is absolutely unsuitable for the empowerment of disadvantaged young people's social participation since there is room for improvement in its pedagogical design to link the supported young people with the context of surrounding societies through utilizing their computing capacities. It is able to be interpreted that the shown limitation rather signifies a demand for the educational support designed based on more social and contextual conceptions that can afford the supported young people an idea (or ideas) about engaging with societies utilizing their computing capacities. In this direction, Schulte's literature (Schulte 2013) will be one of the bases to pursue the possibility of computing education in the light of learner's social participation.

The attempt on realizing educational support on computing and informatics for disadvantaged young people will continue with the purpose of investigating further effect on the young people and also on the practitioners on supporting young people's social participation. To make further attempt fruitful and contributive for the problem, these insights are derived as recommendations for the continuous educational support; practices in the support should be designed considering involving the young people into computing in

social context so as to make more opportunities to link their capacities toward real needs of computing; the “real needs” for computing capacities should be explored under the dialogical relationship among the young people, the practitioners helping young people, and the computing and informatics educators; for the pursuit of sustainable support, an institutional framework to include organizations supporting young people into decent computing culture should be explored. In other words, more holistic support, containing some active problem-solving projects utilizing computing capacities, for instance, that enable the supported young people to find the meaning of learning computing in social context, should be explored and practiced for further empowerment.

Introduction

While the “digital” modifier has an outsize influence in suggesting the engagement, relevance, and ultimately, educative value of storytelling, we want to take a deliberate and critical analysis of these concepts to firmly establish the credentials of this practice, not just as a literacy practice, but also as a means to expand the boundaries of instruction in a classroom. Here, it would appear that the public imagination is quick to suppose that anything “digitalized” is magically superior to its non-digital counterpart. Digital storytelling, or storytelling more generally, can fulfil *axiological* purposes for learning, along with creating an instructional context that can be deeply meaningful to learners. We situate these claims in the nature of stories, and the nature of knowledge itself, but nonetheless argue that the end result is

not the linear sum of these parts – while synergistic gains are possible, the possibility for interference also exists. Educators interested in this field need to be clear about the choice of components chosen, and what trade-offs they may be getting.

What Is Educative?

It is easy to forget that mass public schooling, which we most often associate with the term “education,” has not had a very long history, and that its origins and even much of its current intent has been (and continues to be) one of efficient preparation of a state’s citizens for the world of work. While this pragmatic purpose remains a legitimate one, it must nonetheless be recognized that other particularly liberatory goals for schools exist, such that job preparation remains but a subset of the possible educative goals possible for schooling. Rather than seeing schooling as a gatekeeping process of selective retention of “talent” in specialized fields of work, *education* directs us towards an increasingly wider sphere of participation in social life of the wider communities in which we live. In this regard, we need to recognize that some activities of schooling can be mis- or even anti-educative. For instance, given the high demand and perceived status of work in high technology, it can be easy to fall into the trap of supposing that any sort of schooling activity that involves rehearsal in the technologies *du jour* must benefit the student; even better if the particular technology is in active use by members of a highly paid profession. The trouble with such an approach lies, in essence, with the inherent unpredictability of the future; given the persistent preoccupation of purveyors of technologies to “disrupt” the status quo, job preparation as a goal can appear to be trying to shoot a moving target by aiming at where it used to be.

Even if job preparation were to be taken as a serious goal, it may be helpful here to consider the nature of innovativeness as a goal, given that the creation of novelty (for its own sake?) appears to underlie much of the economic drive of our times, and is likely to continue being important for some time yet. At least in the discipline of design, it has

been acknowledged by leaders and scholars (Kelley and Kelley 2013; Nelson and Stolterman 2003) that innovative advances stand at the confluence of technical feasibility, social desirability, and business viability; and that design intentionality is key to process. To expand on these ideas, we need the philosophical insights of David Hume, who noticed the essential gap between the descriptive and the normative in the field of ethics. Nicknamed Hume’s Guillotine for his observation that no description of the way things currently are have any bearing on the way things *ought* to be, we appreciate this insight if we understand that “innovations” are necessarily statements of ought. The natural sciences and associated technologies need to be interpreted as our very best means of apprehending the world, of describing nature and crucially being able to predict future phenomena. However, the natural sciences must remain mute on how best one ought to deploy these types of knowledge; technological approaches are always informed by purposes outside of the natural sciences. We saw this with a desire to uncover the workings of gods, to admire their work in times past (as in early Islamic civilization providing insights into mathematics, and early paleontology documenting “god’s creation”), to our contemporary desire for nation states to increase economic indicators of “wealth.” In other words, if innovativeness is to be a desired goal of schooling, it may be necessary for schools to not only instruct students in the oft-perceived higher status scientific and technological knowledge, but to also help students develop a more nuanced understanding of desirable intents, persuasive narratives, and philosophical rationales for wider senses of purpose. Stories are the answer to the question “Why Innovate?” – we do so not because the technology leads us to do certain things, but because stories told by innovators tell us it ought to be so.

This leaves us with a particularly interesting position on the educative value of digital storytelling: we believe digital storytelling serves not just as a means to engage students with contemporary technologies, or as an extension to well-established critical literacy approaches. Specifically, digital storytelling, or storytelling more

generally, provides students with a rich context to develop, debate, and discern the correctness of particular intentions. Digital storytelling is an education not merely in the techniques and technologies of telling a story, it is also an education in axiological persuasion, updated with contemporary technologies that affords producers and consumers of stories with media and phenomenological experiences not available to classical means of communication.

In what follows, we develop our argument by first elaborating on the nature of story. The essential contention here is that stories are always vehicles for particular axiological positions, and as with any particular value system, these values are always contextualized to time and space. We return to the above argument to discuss the nature of innovation or the creation of new knowledge, to discuss the distinction between different forms of knowledge. Here, we want to argue for the necessity of different ways of knowing in the service of education for ever-widening realms of participation. No discussion of values, narratives and identities can be complete without referencing the work of critical literacy and scholars in multimodal studies. We use some of these ideas to illustrate the significance of new media: significantly, if we agree with McLuhan and Fiore (1967/2001) that “the medium is the message,” particular media choices can connote distinct value messages too. Finally, to conclude, we discuss some pragmatic issues surrounding the deployment of digital storytelling as instructional technology in the classroom.

What Is a Story?

Stories matter. Whenever we create, listen, view or retell stories, we access key and distinctly human ways in which we inherit our knowledge and values (Eisvaran 2013). We also expand and transform who we are (Tendero 2006), describe, define, and analyze what we do (Kress 2003), and formulate what we can experience and understand about ourselves and others (Jewitt 2002; Turkle 2011). Yet, given their antecedents in language, society and culture, stories and storytellers are

never innocent. Further, storytelling epistemologically, ontologically, and morally is rarely disinterested or neutral. There is always a point to a story but who gets to tell or create one depends largely on who they are, where they are from, what the story is about, and where it might lead us. Indeed, even what counts in a story is moot. This is particularly true in the combined case of education and the use of digital technology as we illustrate shortly.

Storytelling in education (language arts, especially) is longstanding (Morgan and Rinvolutri 1983) but the recruitment of technology enabling learners either working individually or collectively to combine text, sounds, music, images, gestures, and movement in their stories is a relatively recent curriculum innovation in most school-based subjects. Essentially, the rationale and impetus for Digital Storytelling (DST) is expansive, all-inclusive (Ohler 2008), and necessarily distinctive (Hull 2003; Hull and Nelson 2005; Jenkins and Lonsdale 2007) largely due to our particular understanding and biases concerning what counts as knowledge and how it is manifested in particular disciplines and subject areas for specific instructional purposes. These are fundamentally pedagogical issues.

According Morgan and Rinvolutri (1983, p. 9) “[s]tories are everywhere,” but behind their ubiquity lies a complex – and often unquestioned or unexamined – web of characteristics, purposes, and social investments. As a type of text, a story may be a factual or fictional recount of events, an incident, a statement of facts relating to a particular situation, a rumor, a lie, or a testimony, and so on. Stories can be, for example, fun, serious, frivolous, political, judgmental, controversial, and dangerous (Ohler 2008) in the sense that we can be “taken in” by them and their portrayals for better or worse. Stories, then, are never innocent or unconcerned and their impact or influence depends on several factors relating to storytelling. Three of these include structure, purposes, and the delivery. In terms of their multivariate structures, storytellers, especially in narratives and certain types of novel, characteristically have a plan or a plot in mind. Stereotypically, this might involve action involving a quest, conflict-resolution, or in

the case of the *bildungsroman*, character formation or coming-of-age. In addition, opportunities, challenges, and goals presented to central characters and events often involve conflict, growth, and climaxes which result in transformations from humble beginnings, to complicated middles and unexpected (but happy) endings. For instance, we often view the trials and tribulations of the reluctant hero or the nascent genius as particularly intriguing, thought-provoking, and entertaining. We might even wonder, when the structure of a story is “good,” what we might have done or thought in a similar situation to that of a favored protagonist.

We note that some but not all stories in their apparently wide-ranging variation, nonetheless following particular logics: the hero gets the girl, they live happily ever after, the villain is killed, and so on. As a consequence, we often are taken aback and follow along in rapt attention to stories that present dramatic deviations from well-worn narratives. Either that, or we perceive something to be “off” about a story with an unconventional narrative. Whatever the case, these stories are not merely entertainment; they are acts of communication and rely upon (and communicate) societal expectations of what constitutes orderly, sensible, and reasonable trajectories of human behavior, even if the stories are not about them. The story of the Garden of Eden, or any creation mythology, for instance, is decidedly not an innocent story about the happenings of a time past – it presents itself as an explanation for why the world is as it is and how we ought to live.

The centrality of narrative to our understanding of our life trajectories has also been a core principle for a form of qualitative investigation (Clandinin and Connelly 2000; Conle 2000; Polkinghorne 1988; Smith 2007). From this perspective, humans interpret meaning to the apparently random string of events that occur in their lives by fitting them into narrative sequences that make sense. We are literally the authors of our own stories, interpreting new events within the logic of the narratives to date, and reacting to conserve the storyline and identities of who we think we are in our stories – hero, victim, bystander, and so on. Such an approach gives a

significant ethical purpose to broadening students’ repertoire of possible story lines; for instance, it would be hard for a student to understand other ethnicities if she were surrounded by dehumanizing narratives. Indeed, it has been observed that a common precursor of genocide has been the promulgation of dehumanizing narratives by state agencies (Edward Day and Vandiver 2000; Neilsen 2015). An educative approach could help students appreciate that a particular narrative “does not have to end this way,” that alternatives exist to the currently acceptable way of seeing things.

If we were to apply Bakhtin’s (1986) theory of speech genres to stories, then each and every story told would be considered a string of utterances (where an utterance is a unit of meaning in a chain of others’ utterances that precede and follow it) sited within a broad social, historical, and dialogized framework of communication. As Bakhtin (1986, p. 95) states, “An essential (constitutive) marker of the utterance is its quality of being directed to someone, its *addressivity* (emphasis in the original).” An addressee can be an immediate participant-interlocutor or a more distant “audience” in time and space. Thus, with each telling or retelling of a story over moments in time, a new link in that particular story’s chain of utterances is added and fused to it. Furthermore, and vitally importantly, as a story’s chain of utterances extends and the circle of addressees expands, we create new meanings that are located in particular time/space configurations. Thus the meanings of stories – even though authorial intention is important – are always shifting, developing, and reliant on the contexts and social situations in which they are embedded.

Even ostensibly “identical” stories take on different meanings – the same creation myth justified the oppression of women, and explained the problem of evil. We interpret the random flow of events in our lives in terms of narratives that give it structure; things happen for a reason, and we proceed to act in particular ways because the way the tea leaves fall compels us to.

More generally speaking, stories do not always need to offer explicit ethico-moral messages of

purpose, but rather, within the constraints of the way in which stories are structured, and made intelligible to audiences, need to be thought of as a meaningful interaction between the author's intent and the cultural norms of the addressee community. Indeed, as far as fidelity goes, not everything a storyteller intends is always conveyed as planned; our meanings can be difficult to discern, at times due to the contingencies of time, space, and context. For example, the "same" story told in a men's locker room is potentially related but not identical to a similar recount of a particular set of events at a wedding party or an after-dinner chat.

If we accept these points of view, then storytellers stand in a special relationship to the stories they tell. Put briefly, even when the content of a story may not coincide personally, storytellers are, nonetheless, by virtue of their enactment, an essential part of the stories they tell. In fact, when a story is told (even one that is familiar) we often learn something of the storyteller in relation to what he or she may think, feel, know, or value at a specific point and time. We can also claim the same idea for the stories we hear and watch.

In summary, while stories may be commonplace and involve the telling of events or the conveyance of knowledge and information in recognizable and accepted formats, they are neither static nor impersonal entities. Rather, the components of a story involve both the story and the teller, and this, we contend, plays a major part in understanding what a story is about, its importance, purposes, and implications. These points relate to stories and storytelling in education as much as they do to novels, histories and jokes, etc. Stories are always invested, never impartial, and characteristically have a series of points to make in particular ways about who we are, and what we believe and value. It is the peculiarly contextualized nature of values that make an education in stories an important one. Simply knowing a limited set of stories, one type of narrative, provides for an unnecessarily narrowed version of purposes, intents, and relationships. Learning to tell stories provides one with opportunities to ponder about the relative valuing of particular courses of

action, their ethical appropriateness, and their aesthetic value.

Values and Education

It should not be too surprising that the language arts and the humanities appear to be natural venues for value education (for instance, in school subjects such as citizenship and moral education). The apparent appropriateness of stories for communicating certain types of knowledge hints at underlying structural differences between different forms of knowledge. At least the prominent sociologist of education Basil Bernstein (1977, 2003) has noticed that a distinction, quite coarsely, between what he termed as horizontal and vertical knowledge. Verticality refers to the capacity of a knowledge form to build "upwards" as in a form of accretion—for instance, knowledge in the natural sciences tends to be built upon prior findings. On the other hand, horizontal knowledge tends to develop via a radical break from prior traditions—Bernstein used the example of knowledge in sociology, where multiple interpretations of the same phenomenon (the nature of social reality) was more likely than in the natural sciences. Without going too far into what may essentially be the problem of demarcation (Pigliucci and Boudry 2013; Popper 1999), it is nonetheless pertinent to note that significant enough differences exist such that it is important for educators to have an understanding of these issues that can influence the way we design and communicate these types of knowledge to students. For instance, if we understand sociological knowledge to be largely a matter of interpretation, and that what is deemed to be correct a matter of social convention and always up for contention (a corollary of the horizontal characterization), then it is possible that what is known becomes less important than the kind of knower that we desire our learners to be. Indeed, much of Bernstein's work has focused on the social consequences of the differential distribution of high-status knowledge, which necessarily requires researchers to come to terms with the nature of these types of knowledge in themselves.

When we teach students to tell stories, we need to acknowledge the form of the pedagogical intent – not of necessarily communicating particular knowledge claims about empirical phenomena, but more of causing someone else to become a particular kind of knower, placed in particular relationships with the phenomena at hand. While the technical aspects of storytelling can appear prominent, especially since assessment of technique can be perceived to be more ‘objective,’ it is rather our contention that knower relationships with truth claims are currently under-developed and require more attention in schools. This is not to say that there is a shortage of research, as we will discuss in the next section.

It should be obvious here that differential distribution of power involved in the teacher student relationship will have significant influence on the result of this pedagogical interaction. What the teacher believes to count as a legitimate story or story components can have an outsize influence on the eventual learning outcomes of the activity. For instance, Towndrow, Nelson and Wan Fareed (2013) relate the school assessment experiences of Jeremy, a Singaporean schoolboy who created a digital story about his mother’s life of growing up on a public housing estate. In terms of draftsmanship, his hand-drawn scanned images were deliberately sparse and non-naturalistic (e.g., stick figures and two-dimensional rectangular buildings) to convey and visually reinforce the nostalgic-reflective theme of a particular childhood from a young person’s perspective. Jeremy’s teacher did not recognize these features of the story’s design and marked him only averagely according to a standardizing rubric under the category of “ICT usage – Images and Sound Track.” Apparently, his “artlessness” was misconstrued as a lack of ability and maturity. While we would not go so far as to say that we are left in a dilemma in a situation such as this, it is not hard to imagine a situation where we would be. It is quite clear here that the teacher failed to see Jeremy’s departure from aesthetic norms for its creative intent; yet, would it be hard to see another situation where a student “does not get it,” and what is really lost as a consequence?

If we consider a goal of education to be that of literacy, it can be conventionally understood that literacy entails a set of skills to master. Broadly, when we describe a person as literate, we tend to envisage someone who is educated, cultured or competent in a particular subject area or domain. The implication is that anyone who is unable to meet the standards – for whatever reason(s) – fails to meet what it takes to be a fully functioning member of society. There are others who have an even more encompassing and demanding viewpoint. For example, according to Freebody and Luke (2003, p. 53), literacy refers to “... the extent to which people and communities can take part, fluently, effectively and critically, in the various text- and discourse-based events that characterize contemporary semiotic societies and economies.” This is a complex, multifaceted and embedded phenomenon, as Freebody and Luke continue to explain (p. 53): to be literate is to be a participant in literate societies, which are, “... themselves composed of a vast range of sites, locations and events that entail print, visual and analogue media.”

Moving even more widely, Comber and Kamler (1997, p. 1) suggest that literacy is essentially socially constructed, and we can explicitly locate it in institutional contexts where its “... uses are never neutral or innocent, that the meanings constructed in text are ideological and involved in producing, re-producing and maintaining arrangements of power which are unequal.” Literacy, then, is something we create and is socially invested at multiple levels of interest for particular purposes that we define for different reasons. There is also a crucial sense in which contemporary literacy involves far more than the search for static meanings residing within written texts towards their active transformation via readers’ interactions, interpretations, and thinking (Hiebert 1991). Moreover, culturally appropriate ways of thinking have become important in developing literacy beyond focusing on reading or writing, *per se*.

And so, in order to help students develop relevant and meaningful literacy practices, teachers would need to understand numerous varieties of literacy thinking as manifested in different

subject-areas, societies, cultures, and environments (Langer 1991; Rassool 1999; Unsworth 2006). Thus, the forms, functions and uses of literacy are never free-standing, nonpluralist, or disinterested, a priori, by factors relating to the technologies of reading and writing alone (Dubin and Kuhlman 1992; Goody 1977). For example, under this vastly expanded purview, even learning to play a computer game might well be a literacy in its own right (Gee 2004).

The role of educators in these interactions needs careful balance between the poles of communicating canonical interpretations and supporting and developing students' perspectives. Here, it would be necessary to include more recent perspectives on the nature of knowledge and its role in society. For quite some time now, the recognition that horizontal knowledge forms are ruled by a certain sense of social convention, and hence arbitrariness, has not escaped advocates of social justice. Neatly encapsulated as a conflict between knowledge of the powerful and powerful knowledge (Maton and Moore 2010; Young 2008; Young and Muller 2007), earlier advocates believed that *all* knowledge was a matter of social convention, and that truth only existed because of power relationships which were often unfair. More recently, and in contrast to the above, scholars have been realizing that this position can be taken too far, and that there exists knowledge claims that, while ultimately based on social convention, are not completely arbitrary. In fact, and especially for knowledge claims in the natural sciences, the empirical nature of many knowledge claims produce obligatory boundaries to what may be socially constructed. Such was the conclusion of researchers such as Laudan (1996), and more recently Collins and Evans (2017), and Collins, Evans and Weinel (2017) – essentially, while we acknowledge scientific knowledge to be socially constructed, and that the practices of certain scientists to be less than exemplary, this should not cause us to detract from the ideal of the minimization of arbitrariness, or, in the worst excesses of the relativist line of thought, agree that the contemporary arguments against vaccination have equal merit to the scientific consensus on that issue.

The use of storytelling as a means to teach scientific and technical content has been deployed as a means to increase student engagement, or (better) as a means to emphasize the conflicts that often arise in the use of science and technology in societies. Here, educators can tread a fine line between either communicating the scientific knowledge too zealously, or overly problematizing knowledge claims. In either case, careful attention to the nature of knowledge claims is required by the educator.

New Media and Multimodality

Conventionally, new media encompasses the networked information and communication technologies that emerged in the late twentieth century. Nowadays, in contrast to longstanding one-to-many media platforms (e.g., radio, television, and newspapers), new media are typically the many-to-many social and widely distributed platforms we use for creating, sharing, discussing and modifying user-generated content. Jenkins et al. (2006) note how new digital technologies are changing the way young people learn, play, socialize, and participate in civil life. New media are also changing perceptions about individuals' identity and what they can potentially become – or not – through constant on-line connectivity (also see Dede 2005; Gee and Hayes 2011; Healy 1999; Postman 1993; Turkle 2011).

A central characteristic of the newness of new media is not necessarily associated with their novelty but lies rather in the empowerment that comes from making meaningful decisions (Jenkins et al. 2006) and control-taking (Shapiro 1999). Indeed, some would contend that new media – through the central elements of globalization and active participation – allow individuals to personalize information by manipulating and overcoming the limits of time and space in hitherto unprecedented ways (Shapiro 1999).

By the mid-1990s, media and digital technology integration gave rise to views of literacy incorporating a multiplicity of semiotic elements for communication – meaning-making production and interpretation (cf. Cummins et al. 2007; Gee

2009; Warschauer 2006). For example, when reporting the design and meaning-making potential of multimodal authoring, Hull and Nelson (2005) show through fine-grained analysis how Randy, a Californian multimedia artist, combined poetry, photographs, images, jazz music, and rap into an autobiographical tapestry and social critique of life in the bay area of San Francisco.

Interestingly, while Hull and Nelson's (2005) research illustrates the communicative potential of multimodal composition by a minority youth member in a tough and challenging urban context, it is equally the case that new media authorship can be restricted and hindered by textual conventions and taken-for-granted categorizations. For example, writing within the field of learning English as a second language, Nelson (2005) shows how a Mandarin-speaking student named Bonnie became very self-conscious about what she thought her audience might expect to see in her multimedia-based story about living in three distinct countries. At one point, she chose an online image of a pagoda to illustrate the Taiwanese flavor of her previous cultural surroundings even though she knew from personal experience that this building was not as grandiose as it appeared in the shot she had chosen. Nelson goes on to suggest that the use of cultural and societal stereotypical representations may be an instance of an overaccommodation of audience expectations (in this case what others perceived to count as or represent Taiwanese-ness) and thus serve as self-imposed limitations on authorial voice and intention.

In sum, new media and changed personal situations (Birkerts 1994) profoundly challenge the long-established logics of literacy and teaching rooted in essayist (pen-and-paper) and print-based epistemic authority (c.f., Kramer-Dahl 2008; Kress 2007). Further, given its all-embracing nature and historical context, multimodality – as part of the larger multiliteracies agenda (New London Group 1996) – complicates traditional notions of authorship, meaning making, and authenticity. Indeed, for some, the established and (at times) unquestioned literacy practices and procedures of classrooms, and beyond, are proving to be inadequate and insufficient. They

not only disappoint young people whose expectations of engagement and interaction are greater and distinct (Brooks-Young 2010; Jukes et al. 2010; Prensky 2010; Ware 2008), but also suggest shortcomings in directing instructional and pedagogic momentum towards the development of the new domains of work, identity, changing subjectivities and citizenship required in the twenty-first Century (Ajayi 2009; Hull and Katz 2006; Ohler 2010; Lam 2006; Tapscott 2009).

Concluding Remarks

In sum, we believe our portrayal of the educative value of digital storytelling is neither absolute nor deterministic. Rather, we acknowledge and celebrate the potential that storytelling has to expand the boundaries of learning and instruction axiologically and agentially. Stories are not limited by content or subject area and do not only depend on learners' linguistic or aesthetic capabilities. We attribute these effects to a range of factors including the nature of different types of knowledge, the potentialities of new media and multimodal communication, and characteristic conjunctions between a story (structure and content) and storytelling (delivery). Overall, we contend that given the complexities of story creation and telling, stories can never be merely the linear sum of their parts.

While educative and synergistic gains are possible, there is an accompanying risk of stymying digital storytelling by limiting its scale and scope. For example, this may happen when digital storytelling is viewed as a largely technical enterprise where fidelity to accepted and common story structures (characterization, plot, and content) and prowess in using computers and software are valued higher than artistry and unconventionality. A related issue concerns maintaining an essayist's view of literacy relating to storytelling as ways of demonstrating linguistic and/or conceptual mastery.

It is pointless to deny or decry the instructional needs of formal education to teach and test learners. Yet, more broadly, as far as digital storytelling is concerned, we encourage educators

interested in this field to be clear – pedagogically, theoretically, ethically, and practically – about their decisions and choices in instructional design, and to become more aware of the trade-offs they may enter into and receive.

Educators and Children Perceiving Affordances with Working Technologies in Early Childhood Settings

Jo Bird

Cameras; Computers; Early childhood; ICT; iPads; Play

Introduction

The range of digital technologies available in early childhood education (ECE) settings for children birth to 5 years has increased over the last decade. While somewhat limited literature exists across the ECE field, researchers have now begun to explore how children engage with technologies, rather than concentrate solely on the quantifying screen time exposure and impacts (Bird and Edwards 2015; Marsh et al. 2016). More

specifically exploring how young children engage with provided technologies provided in ECE settings will increase the practitioner's knowledge base and effectively promote children's learning with technology devices. The types of technologies provided for children's use are detailed below, along with professional learning, the perceived affordances with devices, how children respond to provided technologies, and a discussion on the effect of changing perceived affordances.

Working Technologies Provided and How They Are Used

Within early childhood centers, both imaginative and working technologies can be offered. Imaginative technologies are those provided in pretend dramatic play spaces, possibly arranged as home corners, doctor surgeries, hospitals, or restaurants (Bird 2019). In contrast, working technologies include iPads and tablets, still and video cameras, interactive whiteboards, robotics, and coding devices (Bird 2017). With the introduction of the iPad in 2010, ECE settings have embraced these devices for their ease and usability with young children. They are often provided for children's free play, but as yet limited to no adequate support is offered to educators to integrate them successfully within their programs and pedagogies.

While technologies have been associated with negative impacts on young children's health and well-being, recent researchers have called for more comprehensive exploration into how the devices are being used. For example, active participation requires children to design and create their digital experiences rather than be "passive responders" to screens and media (O'Mara and Laidlaw 2011, p. 152). In her doctoral research, Scott (2018) found that children's engagement with television and related media extended beyond just viewing the screen and absorbing what was being fed to them. Instead, the children danced, sang, and took the themes from media and embedded them into their play. Children adopt their play themes from their everyday experiences, and in the digital age, this includes

technologies and related media. Children also reenact the experiences from their communities as they practice behaviors and act out societal roles that may one day be integral to their futures. Again, these will likely involve technologies and associated digital literacies.

Providing working technologies in ECE settings reflects wider society's uptake of technologies and potentially builds digital literacy links between home and early childhood contexts. Children may be supported to use technologies at home and experience a wider range of devices and practices than those typically incorporated in ECE programs. Children may attend their ECE settings with significant experiential knowledge around technologies and expect to encounter these technologies in their daily learning. However, they may find their ECE setting is void of any devices and play involving technologies is actively discouraged by educators.

Educators' Provision of Digital Technologies

Many studies have explored the reasons for educators' reluctance to provide technologies in ECE settings. The reasons cited have ranged from limited educator confidence, to lack of hardware and devices, scant pedagogical understandings of technologies, to somewhat narrow beliefs about the role of technologies in young children's education. As Blackwell et al. (2014) report, educators did not grow up with technologies, so often they do not feel comfortable or confident in sharing technologies with the children they teach. This is slowly shifting. As technologies are increasingly embedded in our daily lives, educators are becoming more digitally literate, such as confidently using devices in their personal lives. The issue is then to transfer their personal skills around technology into their personal lives and into their professional lives in a way that transforms their pedagogical understandings and improves their technology provisions for children.

One contributory factor to increase technology provision in ECE settings is to offer technology-targeted professional learning. Unfortunately,

such professional learning does not always meet educators' needs or reflect the different devices or the cultures represented in the various centers. How this can be achieved is still an area of ongoing investigation. Either way, technologies are an integral part of children's realities and their daily lives, and they employ these digital experiences in their imaginative play scenarios. Therefore, ECE settings must reflect these experiences and support children's understandings of their social contexts including digital literacies.

In exploring how children engage in imaginative play using working technologies, Bird (2017) created new challenges as there are many elements that need to be in place before the technology will allow children to engage in the type of play that educators recognize and value as contributing to learning. Alongside this issue is the provision of these devices and the rules and restrictions educators apply to their use and how they impact children's imaginative play. In the following sections, the affordances of the provided technologies will be discussed from both the children's and the educators' perspectives. Also discussed are the effects the perceived affordances have on children's play and learning and the rules and restrictions educators place on the device usage.

The Perceived Affordances of the Provided Technologies

Gibson (1979) explained the concept of affordance as relating to the individual perceiving the affordance. First, the individual must perceive an affordance in order for it to be recognized. The perceived affordance is determined by the individual through environmental stimulus information. In relation to children's technology use, stimulus information may include the availability of the devices, the rules and restrictions that may influence usage, and also the child's prior device knowledge or skills.

Increasingly in ECE settings, devices or working technologies are provided and promote affordance. The devices might include computers, iPads and tablets, cameras both video and still,

and digitally enhanced toys. How the devices are employed ranges from educators using iPads to research current topics of interest or to play songs to children being allowed free access to iPads to play and take photos.

Children's Response to Provided Technologies

Children appear to respond to the technologies in three ways. The first is to *accept* the technology as provided; the second is to *negotiate* the rules and restrictions applied to the technology in order to play in the way they choose; and the third is to *abandon* their playful plans. When children *accept* the technologies, and use them in their play, they perceive the affordance of the technology to play imaginatively. Often educators apply rules and restrictions around children's use of technologies and children perceive affordances with the technologies, but at times children need to *negotiate* the rules before their imaginative play can be realized. For example, children might attempt to negotiate a time restriction and remain at a device even after the timer has expired. Another restriction might be that children are not allowed to stand behind a device and watch another child having a turn. Children have been observed to negotiate this by remaining in situ after their turn has finished. If the children are not successful in *negotiating* the rules and restrictions placed on devices, they typically *abandon* their play.

For children to perceive affordances with devices, other "mini or aligned" affordances are required to be in place before the main affordance can be perceived. This is similar to executing a planned affordance. For example, airport baggage screening processes actually incorporate many affordances that need to align to promote passenger safety (Pols 2012). In the same way, children's use of working technologies needs many affordances to align for the children to be able to play imaginatively and fully explore digital literacies through play.

Further, children and educators perceive the working technology affordances differently.

Children perceive that the working technologies can afford them imaginative play and display this through their *acceptance* and *negotiation* of the rules and restrictions associated with each device. Interestingly, educators do not perceive that technologies can afford imaginative play, often displayed in their lack of direct engagement with children around technology play. I argue this is a key concern, as educators seem to be missing important learning opportunities through their lack of direct engagement with children as they playfully interact with working technologies. Research by Furman et al. (2018) found that children's learning increased when educators interacted and supported learning on these devices. The first step in executing a planned affordance is for educators to recognize the potential affordances of working technologies for children's learning, the second is that educators need the pedagogical skills to support the learning potential, and then, finally the time required to ensure interactions occur to promote learning.

A Change to Perceptions

If the educators perceived the affordances for the children's imaginative play, their pedagogical strategies would support and encourage children's engagement with the technologies. Instead, a tension appears between the children's perceptions of the technological affordances and the educators' lack of perceived affordances. This tension also highlights a difference between the working and the imaginative technologies (Bird 2019). In Bird's study, educators identified play with imaginative technologies as corresponding with their personal definition and beliefs about "real play," and therefore they knew how to pedagogically scaffold the play. When asked how they supported and extended children's working technology play, educators often did not know or referred to the technical assistance they provided in making the device work efficiently.

Technologies are often viewed differently to other activities in ECE settings. When children are engaged in collage or construction activities, educators do not monitor the time being spent

there. In contrast, timers are often used to control the time children spend on working technologies. The covert message received by the children is their technology involvement is not as valued as other activities. Children see the computer and iPad and what they can afford "as important to their play and learning" (Bird 2017, p. 110), but in contrast, educators can see them as a special treat to be utilized on rainy days. This difference in perception results in rules and restrictions around their provision that constrains the children's abilities to engage in imaginative play with the various technologies on offer. The educators' views about technological affordance are in opposition to the long-held belief that play is the vehicle for children's learning in ECE settings. Instead, if educators viewed children's engagement with technologies as play, they would actively scaffold the play, just as they do around play with imaginative technologies. As acknowledged in recent research, educator involvement around technologies is not only required to develop children's skills with device functions (Bird and Edwards 2015) but also to build conceptual knowledges and extend children's understandings about what is occurring on the screen (Reid-chassiakos et al. 2016).

Another area of concern is the often underrepresented observations and assessment of children's learning and development in educators' documentation of children's engagement with the technologies. Educators describe not understanding or feeling confident with what children actually "do" with technologies, and therefore observations tend to be statements of children using technologies, rather than what they are learning or the skills they might be developing. This concern aligns with two points established in current literature. The first is that educators do not fully understand children's engagement with technologies and what they could possibly be learning, and, secondly, educators lack confidence in recognizing traditional forms of play in children's technological practices (Bird 2019). When educators witness children's technological play, they do not always observe what is actually happening on devices, a critical requirement to recognize play. With technologies increasing in both society and

ECE settings, building educator understandings of how children play and learn with technologies is vitally important. In addition, educators need appropriate pedagogical knowledge to scaffold children's play and learning and to extend possibilities for learning.

Technologies must be seen as integrated into the ECE curriculum, embedded into a range, if not all, activities both indoors and outdoors. In building educator knowledge around ways to support children's play and learning with technologies, the focus needs to shift from "how can I provide this technology" to "how can I actively engage in the activity being provided to scaffold children's play and learning with technologies?" Shifting the educator's focus from the technology alone to either the children's play and learning or to the aims of an activity more effectively builds children's understandings that technologies are one of many useful tools to achieve a specific task. This also strengthens educators' pedagogical knowledge for embedding technologies in all areas of their programs.

Children and educators perceive affordances with technologies differently, and this can be viewed as a continuum. At one end, children perceive the technologies affording them imaginative play, whereas the educators are positioned at the other end of the scale and do not see the same affordance possibilities. The children "were advancing in-step with society's technological understandings and the educators remained stuck in their traditional beliefs and practices of a time when digital technologies were not so prevalent" (Bird 2017, p. 110). The goal of technology provision is to bring the educators' perception of technology affordances for imaginative play into line with how the children perceive them. As previously stated, educators use technologies in their personal lives (Lafton 2015), and what is needed is to encourage them to transfer this knowledge into their professional lives with children.

Conclusion

It is clear that children and educators perceive the affordances of technologies in imaginative play

differently. The barriers to educators' provision can be addressed through research around how children engage with technologies in their imaginative play. Such research findings can be disseminated to educators in ways that increase educator's knowledge and assist them with rethinking their technology-related, pedagogical beliefs.

As discussed at the outset, the research focus needs to shift from children's amount of screen time to the type of activities being undertaken with technological devices. By making this shift, children and educators can focus on technologies being a tool to assist with various activities and learning outcomes, rather than an activity of itself. Changing the focus will assist with embedding technologies into ECE programs and exposing children to appropriate uses of technologies. Discussed in the literature is the notion that children play to practice community behaviors and enact future roles, and by successfully embedding technologies into all areas of early childhood programs, children can practice these behaviors and work toward becoming effective and responsible digital citizens.

Introduction

This entry discusses the Kingdom of Saudi Arabia (KSA), a country with an immense natural resource of oil, the production and sale of which underpins the economy of the country. The country has a rapidly growing population that in 2018 was over 33 million, of which 58% were below the age of 34 years. One consequence of such rapid population growth is that colleges and universities within the country have been confronted with two challenges during the current century: to improve the quality of education and to make higher education available to a vast and increasing number of students.

There have been some key emergent issues in that scenario that initially led the Ministry of

Education to permit universities to develop wholly online degree programs. First, the physical size of the country makes it difficult for all potential students to attend university campuses, especially women who were typically reliant on male relatives or hired drivers to transport them. Second, the national social mores did not allow for coeducational learning, leading to the development of segregated gender provision. More importantly, however, was that there was limited capacity within Saudi public universities to cater for those who are entitled to study in higher education. This led the Ministry of Higher Education to identify online provision as one possible answer to these challenges and to establish the National Centre of Electronic and Distance Learning (NCEL) in 2006 to create and categorize change in respect to eLearning and distance learning materials. Subsequently many universities began creating wholly online degree programs, supported by government funding, to the extent that 15 out of 25 public Saudi universities were offering such programs by 2013. By 2014, the number of students enrolled on wholly online programs reached 350,000, which constituted 33% of higher education students at Saudi universities, with more students enrolled on such courses than those receiving traditional instruction.

Students who graduated from such programs suffered, however, from the degrees not being accepted as valid in some private sector companies, for teaching in schools with other Arab countries in the Middle East or even progressing to postgraduate study (Ministry of Education 2014). In addition, online degree programs were considered to have challenges which disaffected learners and had often proved unpopular in KSA with most students lacking the requisite skills to make use of such learning methods (Al-Mousa 2004).

In 2014 the Ministry of Education (MOE) published a commissioned report which questioned the value of wholly online programs and concluded that such provision in the kingdom was effectively out of control and had become disconnected from the needs of the labor market (Ministry of Education 2014). As a learning

method and component of the Saudi education system, wholly online learning was considered as no longer fit for purpose, with one study revealing that instructors themselves had little faith in the quality of their own institution's online programs (Al-Draiby 2010). Furthermore, employers (including the government itself) were placing a low value on the qualifications emerging from this provision and a lack of regulation and quality control.

The ultimate outcome of this investigation was that universities were advised by Deputy Minister for Education Affairs not to accept any further students in eLearning courses for the academic year of 2016–17. Instead, the Saudi Electronic University (SEU), the first electronic university in the Arab world and which had been established in 2012 to offer specific prerequisite courses as demanded by the labor market, was to develop “centers for eLearning” throughout the country with the assistance of other universities. Central to this planned provision was blended learning (BL), a combination of face-to-face (f2f) and distance online learning (DL).

The Case for Blended Learning (BL)

A wide range of advantages have been ascribed to BL which is seen as advantageous in comparison to wholly online or traditional face-to-face methods. BL is considered as offering enhanced instructor–learner and learner–learner interaction which includes personalized, timely, and iterative feedback (Hrastinski 2008). BL also avoids the pitfall of DL's potential to become the ultimate in didactic learning with information simply dumped on learners via the World Wide Web (Garrison and Kanuka 2004). With a significant face-to-face component, BL learners are less likely to experience the detachment, demotivation, and distraction associated with wholly online degree programs (Galusha 2011). Instead, BL offers flexible interactions and opportunity for knowledge coproduction (Vaughan 2014).

Additional advantages over face-to-face-only methods mainly concern access and cost as BL

can channel higher education to parts of a population that were previously problematic, including mature students already in employment or those with family responsibilities which makes full-time attendance difficult, so extending the geographic reach. In Saudi Arabia, BL also creates practical possibilities to overcome social and cultural barriers to male–female interactions. A female student can attend and participate in a virtual class with male instructors and fellow students, for example, in a way that would not occur in a physical classroom. On a theoretical level, BL also fits with a constructivist and co-constructivist approach to learning mainly through its ability to facilitate collaborative tasks (Stahl et al. 2006).

Overall, given the problems emerging from the rapid expansion of online degree programs in the kingdom, it is unsurprising that policy makers viewed BL as a viable new path to achieving their objectives. When combined with appropriate quality control BL was considered to offer the Saudi HE system a realistic path to achieving the country's goals. A major element of this quality control was to bring all BL provision under the control of one institution – the Saudi Electronic University (SEU). For the 2016–2017 academic year, public universities were thus instructed by the MOE to cease enrolling new students for their online degree programs.

The SEU Plan

The SEU was already operating at the time the government withdrew its support for eLearning programs that were running in most Saudi public universities. It was established by royal decree signed on September 7, 2011, and rather than delivering programs entirely online the university was to facilitate BL, with three-quarters of course content being online and the other quarter being delivered face-to-face. The royal decree was accompanied by a statement from the MOE that explained that the new public university would provide higher education and lifelong learning with undergraduate, postgraduate, and continuous learning programs under the

supervision of the Higher Education Council (Ministry of Education 2015). On opening the SEU would have three colleges, Administrative, and Financial Sciences, Computing, and Informatics, and Health Sciences. Subsequently, a fourth college, Science and Theoretical Studies, was opened. In addition to the main Riyadh campus, three branches were opened in 2012 in Jeddah, Dammam, and Madinah. On opening the SEU the Director announced that 60% of places at the new university would be reserved for female students. At the time of its launch, the strategic plan was to open 20 branches across the KSA and serve up to 100,000 students in 10 years' time. The SEU divided most of its campuses into male and female locations, employing female instructors for female learners. For the online component, female learners could interact with male instructors and students, as educational segregation does not extend to the Internet.

Such an approach to student learning appears therefore to be sympathetic to the cultural norms traditionally associated with higher education in Saudi Arabia in that it is based on a relationship between instructor and student, thus allowing for a requisite amount of F2F interaction. In this way the SEU strategy seeks to address the potential issues of isolation and alienation found within previous research studies undertaken in the country. In addition, core aspects of the teaching programs were to be “live,” rather than asynchronous, to encourage the sense of student community that can evolve in learning cohorts.

Instruction and course materials were to be exclusively in the English language, a decision which brought the perceived benefit of being able to partner with global leaders in online learning provision such as Franklin University in the USA and the virtual learning environment, Blackboard Learn. These and other providers enabled the SEU to offer a wide range of undergraduate and postgraduate programs designed to an international standard. With such international partners in support, the SEU was expected to be able to deliver successfully a wide range of undergraduate courses and a postgraduate MBA. The use of English only would, subsequently, have more negative consequences in student retention,

however, an issue which will be examined in more detail below.

Admission to the SEU requires a secondary school certificate or equivalent though grades are considered the exact requirement is not published. Unlike traditional Saudi universities and as part of the commitment to lifelong learning there is no stipulation for the recency of the secondary qualification. Once admitted, SEU undergraduates follow a common preparatory year comprising English language, computing, communication skills, basic mathematics, and academic skills. Uniquely among Saudi public universities, students could continue to be employed while studying at the SEU.

The Early Years of the SEU

By the academic year 2016–2017, student numbers at the SEU had grown to 14,485 studying at one of eleven campuses, but this represented a slight fall on the previous academic year which suggested the planned trajectory toward 100,000 students was overly optimistic. The main reason for this can be seen in data publicly released by the SEU which reveal that only a small proportion of students in the common preparatory year progress onto their major degree pathway either because they do not pass the requirements for English (or other components of the first year) or because they drop out for other nonacademic reasons (SEU 2018). In the 2015–2016 academic year there were 10,233 students following the preparatory program and 4,844 in other years following their major or undertaking postgraduate studies, meaning that most students enrolled at the SEU were in their first year. In normal circumstances with so many students poised to commence their major degree program in 2016–2017, a huge rise in student numbers taking their major degree pathway would be expected. Instead, major student numbers fell back to 4,153. Allowing for some graduations, it appears that a negligible proportion of preparatory year students were progressing (SEU 2018).

The SEU was established to widen access to HE to mature students who had already embarked on their career or who had existing family responsibilities. The entry criteria are purposely set at a low level on the basis that a mandatory preparatory year could bring them to a satisfactory level in the skills they will need to complete their major degree pathway. From the university's data it appears, however, that all too often this does not happen (SEU 2018). It is recognized that attrition through changes in life circumstances may be unavoidable with an SEU student who is likely to be older, already be employed or already have family responsibilities. A change in job, a pregnancy, getting married, and moving home are all potential causes for withdrawing from a study program. In addition to this, Saudi HE, in general, has a problem with student retention and low graduation rates. Aljohani (2016), for example, analyzed institutional data and concluded that the average graduation rate for Saudis on 4-year program was 65% and falling to between 35% and 50% for those on 2-year programs.

Clearly, student retention is an issue in Saudi HE. In comparison in the UK only 6.4% of first-year undergraduates failed to progress to the second year of their studies in the academic year 2015–16 (HESA 2017). The rate of student attrition at SEU is high and thus a threat to the ambitions declared at its launch. The lack of an English language admission criterion would seem the most plausible explanation with many students unable to reach the required level by the end of the preparatory year, a level that is equivalent to an IELTS score of 5.5. At Saudi Arabia's traditional public universities, there is usually a requirement to hold a recent English proficiency certificate of between IELTS 5.0 and 6.0 before commencing the preparatory year.

There are also issues related to the stated objective of reserving 60% of its places for female students, with current data showing that only 35% of its students are female (SEU 2018). The reason for this divergent outcome can only be speculated on, as no study has been conducted. However, at

the 2015 International Conference on eLearning and DL held in Riyadh the Saudi Deputy Minister for Education Affairs, Al Ouhali, reported that across all eLearning in the kingdom two-thirds of learners were male, meaning the SEU outcome seems to be in line with the previous DL balance (Ministry of Education 2015).

The Challenges of BL at SEU

Following a BL program requires greater self-direction than one using traditional f2f methods and this raised the issue of a conflict between BL and Saudi cultural norms. Smith and Abouammoh (2013) explain that the rote learning of information by passive learners is a fundamental element of Saudi culture and religious teachings, as are structured lifestyles and work environments. This would suggest that self-direction may be challenging for some Saudi learners.

While the lack of English language skills has been given as the prime reason for low student retention rates in their first year, individual capability with the use of information technology is also a key component of the preparatory year and some students without a background of such skills appear to find this challenging. The decision to deliver all programs in English had the benefit of SEU being able to draw on the tried and tested technologies and practices of a range of global leading providers, enabling the university to populate its programs with content quickly and draw on non-Saudi instructors and instructor training services. It immediately exposed the university to certain risks, however, that appear to have called its ambitious development plans into question. On the one hand, it vowed to broaden access to higher education, while on the other hand delivering courses in English is restricting success only to those with a high level of English proficiency. Having a high proportion of preparatory year students failing to commence their major degree program in their second year is an inefficient use of resources, not to mention a discouraging experience for the students themselves.

Lessons from the SEU Experience

Improving English language instruction to get more students over that hurdle is one option. From the outset SEU has partnered with its global providers and SEU students have access to their online English school English Live. However, it seems that achieving a substantial increase in proficiency in just one academic year is beyond many students. Another option is to introduce a proficiency requirement at the point of enrolment for the preparatory year. With a common understanding that it takes 1 year to improve IELTS by a score of one point, it would seem necessary to have a higher requirement for IELTS first enrolling. While this would exclude many such a requirement would be likely to improve progress to their major degree program.

A further option that could help the SEU achieve its access goals would be to deliver some programs in Arabic. While Saudi Arabia's longer-term ambition (Vision 2030) is to develop an outward looking country with a diversified economy, some parts of that economy are never likely to need English language skills including those delivering services to the local population. The challenge here would be one of capacity to design and populate such programs as their international partners would probably not be able to help.

Concluding Thoughts

The establishment of SEU was a bold initiative initially designed to address the problems that had arisen with eLearning in the kingdom while taking advantage of the technological opportunities that are transforming learning around the world. A very early decision was taken to adopt BL as the preferred model of student learning, and while it is true that initial plans have failed to materialize as hoped, it remains a viable ambition for the Saudi HE system.

The key issues to address do not include the concept of blended learning as the arguments for

its adoption can be deemed to be secure. SEU, instead, will need to explore how to deal with admission requirements, which language to use for the degree programs, how to improve retention (which may be connected to the first two issues), and why the proportion of female students remains at similar levels to those witnessed on the previous wholly online programs.

Empowerment and Disempowerment in Peer Observation Within Pre-service Teacher, Technology-Assisted Integrated STEM Education

Duncan Symons and Joanne Blannin
Melbourne Graduate School of Education,
The University of Melbourne, Carlton,
VIC, Australia

Introduction

STEM education has been receiving increasing attention over recent years. It is seen to offer the potential to enhance development of various “soft” skills”; sometimes known as twenty-first century skills (Cronin 1996). These skills include, but are not limited to, creativity, innovation, critical thinking, decision-making, problem-solving, metacognition, collaboration, and communication.

STEM education is claimed to present a solution to preparing young people for jobs of the future. The Chief Scientist’s Office of Australia reports that there is a growing demand for STEM qualified employees (Prinsely and Barayai 2015).

Additionally, STEM education is seen as a potential approach to reversing high levels of disengagement with science and mathematics. Disengagement with these areas is reported to begin in primary school (Sullivan et al. 2006; Martin et al. 2012).

With the promise of STEM education as a rationale, academics within the University of Melbourne, Melbourne Graduate School of Education, working alongside academics and scientists from the Faculty of Science, the Gene Technology Access Centre (GTAC), the Victorian Space Science Education Centre (VSSEC), and the Melbourne Museum, have planned and facilitated an elective subject with preservice teacher education students (PSTs) with an integrated approach to STEM education as a focus. The facilitation of the elective subject has been funded through the Reconceptualising Maths and Science Teacher Education Programs (ReMSTEP); an Australian

Government program funded through the Office for Learning and Teaching (OLT).

Throughout the 3 years the elective subject operated, academics teaching in this elective were interested in helping students to develop Professional Learning Communities (PLCs) to support their STEM planning and teaching. The context of the subject seemed ideally suited to the facilitation of PLCs given that teams of PSTs collaboratively taught each classroom of school children. A key component of the PLCs developed in this subject was the opportunity for students to observe each other teach and provide peer feedback. While observing each other teach, pre-service teachers (PSTs) used their personal mobile devices to record observations on “Padlet (www.padlet.com)”; a digital media board that enabled individuals to express their thoughts on a common topic through real-time, text responses.

These responses were coded and analyzed to explore the types of feedback PSTs provided to each other. This supported the development of an understanding of where, based on learning areas, and how, based on the language used, PSTs directed their peer feedback when working in PLCs.

This analysis also explored the implications and evidence of power relationships between PSTs, who might be assumed to identify as holding similar levels of influence and power as they all identified as learners in the Masters teaching preparation course.

Upon investigation of literature focused on the impact of peer-observations on learning, it has become clear that a challenge exists in the acts of peer observations. An imbalance in the power (Cronin 1996) exhibited and enacted by those observing has been raised as a critical constraint of this learning strategy.

Facilitators of learning have reported negative feelings that include feeling surveilled by those perceived as holding power over them (Shortland 2004). One outcome of this identified challenge is seen to be teachers resisting change as they face uncertainty when using new pedagogies in their classrooms. Teachers felt inhibited by the perceived power of the observer. In this study we aim to examine whether PSTs equally perceive this power imbalance. We hypothesized that, in

their role as learners within the context of their initial teacher education, the PSTs would value the experience of peer observation feedback differently.

One source of data utilized within this study was a series of three open-ended online surveys. These surveys provided insight into how PSTs viewed the process of engaging in PLCs and providing and receiving peer feedback.

We aim to address two research questions in this chapter:

1. How do PSTs perceive peer observation and feedback, when utilizing online mobile technologies?
2. How do PSTs focus their peer feedback when utilizing online mobile technologies?

In the following sections, we first provide some discussion of literature in the area of tertiary level peer learning and the use of online mobile technologies to facilitate Computer Supported Collaborative Learning (CSCL). Next, we will provide some discussion of the Context and Study Design. A discussion of the Results will then occur and lastly some Conclusions and Implications will be offered.

Literature Review

This literature review is divided into two subsections. The first subsection provides background and discussion of literature supporting the first research question, while also providing discussion of literature closely aligned with the second research question. Where possible, the literature selected is based within the context of research in tertiary settings.

Peer Observation, Peer Learning, and Professional Learning Communities

While there is some variation in conceptions of what constitutes a PLC, Stoll et al. (2006, p. 223) state that “there appears to be broad international consensus that it (PLCs) suggests a group of

people sharing and critically interrogating their practice in an ongoing, reflective, collaborative, inclusive, learning-oriented, growth-promoting way” (Stoll et al. 2006). The establishment and facilitation of a PLC can take many forms. However, a common component of PLCs is peer learning, regularly including peer observation, and peer feedback. In the context of our study, peer observation and feedback was central to the development of PLCs.

“Reciprocal peer learning,” which includes “peer observation,” has been described as “mutually beneficial and involves the sharing of knowledge, ideas and experience between the participants. It can be described as a way of moving beyond independent to interdependent or mutual learning” (Boud et al. 2014, p. 3).

Martin and Double (1998) describe the benefits of this approach in staff professional development as follows:

- Improve and develop an understanding of personal approaches to curriculum delivery;
- Enhance and extend teaching techniques and styles of presentation through collaboration;
- Engage in and refine interpersonal skills through the exchange of insights relating to the review of a specific teaching performance;
- Expand personal skills of evaluation and self-appraisal;
- To develop and refine curriculum planning skills in collaboration with a colleague; and.
- Identify areas of subject understanding and teaching activity which have a particular merit or are in need of further development.

In the majority of literature exploring peer learning and peer observation, there is agreement that feedback and observation should occur in a nonjudgmental, objective, and supportive manner (Boud et al. 2014; Martin and Double 1998; Cosh 1999).

Critiques of the approach, however, contend that the goal of peer observation is easily subverted. Shortland (2004) utilizes Derridean Deconstruction (Derrida 2016) to gain insight into how university documentation relating to the peer observation process can highlight issues

of power imbalance between the observer and observees. Deconstruction is described by Chaffee (2009, p. 80) as “a way of rereading texts to uncover the silences in the history of philosophical and social thought and, as he (Derrida) acknowledges, to create silences of its own.” Shortland (2004) contends that the observer involuntarily is placed in a more powerful position than the observee. Additionally, she argues that peer observation is used, at times, as a method of surveillance and used to ensure compliance by figures of authority or management. She states, “discussions revealed some staff members completing observation documentation simply to comply with the managerial requirements to do so, having not actually undertaken the observation process. A mechanism by teaching staff to highlight their perceived needs whilst minimizing their workload or an opportunity for resistance whilst not misbehaving?” (Shortland 2004, p. 226).

With these critiques of peer observation in tertiary level education in mind, we aim to gain an understanding of PST perceptions of the process in our STEM education focused elective subject.

Mobile Technologies Enabling Computer Supported Collaborative Learning (CSCL)

While there is an increasing volume of literature addressing the use of mobile devices, typically mobile/smart phones, tablets, or in some cases lap tops, in teaching and learning contexts (Ciampa 2014; Ekanayake and Wishart 2015; Fougler et al. 2013), little research exists specifically investigating the use of internet connected mobile devices to engage in collaborative, observational, feedback of peers within teacher preparation courses.

Symons et al. (2016, p. 2) describe Computer Supported Collaborative Learning (CSCL) as taking “place via the vehicle of technology (computers, tablets, mobile phones etc.) typically linked via an intranet or the internet.” Dillenbourg (1999) has explained previously that in order for CSCL to occur, peers who are more or less at the

same level perform the same action, have a common goal, and work together.

The utilization of technology reported in this study suggests an alignment with Dillenbourg’s (1999) description of CSCL. PSTs, who are at the same level, performed the same action of engaging in the planning and teaching of STEM. They had the common goal of furthering the development of their practice and they did so in collaboration with each other and as such were “working together.” Synergies between the conditions required for CSCL to occur and the collaborative, nonjudgmental, shared support and accountability required of PLCs suggests that taking a CSCL-based approach to the use of technology within PLCs is a natural and logical fit. We regard the use of mobile technologies reported in this study as an example of CSCL.

Context and Study Design

As a part of a STEM elective subject, which is undertaken in the final semester of their 2 year graduate Masters level degree, PSTs were required to teach a series of sequential lessons to primary school students taking an integrated STEM-based approach. Across the 3 years in which the elective subject has taken place, PSTs have worked with a number of schools in the inner suburbs of Melbourne, across an age range encompassing all of the primary years.

Before teaching within schools, PSTs have had opportunities to develop an ability to work effectively in PLCs through attendance at lectures and engaging in workshop activities designed to enable them to understand the different approaches that may be taken to establishing successful PLCs. For example, in addition to attending a lecture providing more general information about PLCs, PSTs also attended a lecture (from an international expert in the area) providing detailed information about Japanese Lesson Study (Iksan et al. 2014). They were then asked to draw links and synthesize the various materials.

Following, workshops and lectures, PSTs taught a sequential series of four weekly lessons to year 5/6 students (age 10–13). The data

reported here is taken from a year in which the focus for teaching was on Bees and Bee adaptations. Specifically, PSTs were to facilitate a student inquiry investigating, why there has been a dramatic decrease in bee populations over recent years.

During the teaching of each of the four lessons, a group would observe the teaching group and use their mobile devices to post short pieces of feedback related to the lesson that they were witnessing on “Padlet.” At the conclusion of the lessons, each week, each of the Padlets would be displayed on a data projector and the group that had observed the teaching group would facilitate a discussion providing feedback about the teaching group’s lesson. In the Padlet, users had the ability to upload multimedia and provide real-time succinct feedback to their peers. Notably, some feedback focused on mathematical understandings, while some was focused on pedagogical, technical, and organizational matters.

Across the 4 weeks, each contribution on each Padlet was coded and then aggregated in an effort to better understand on where the PSTs’ feedback was focused. Codes allocated to contributions were, “Science,” “Technology,” “Engineering,” “Mathematics,” “STEM” (indicating a contribution where concepts are integrated across the disciplines) and “General Pedagogy.”

In addition to data derived from the Padlet pages, we utilized qualitative data from three, online, open ended, anonymous surveys to gain an understanding of how PSTs perceived their experience of working within a mobile technology supported PLC.

Results and Discussion

The results and discussion are divided into two subsections. The first provides a number of excerpts of responses to an online survey that was completed by PSTs within the elective. Analysis of these excerpts provides some indication of how PSTs perceived the technology supported peer-observation process that was core to the subject. The following section provides the results of aggregated student peer feedback taken from

Padlet and some discussion of how these results suggest that PSTs focused their feedback.

PST Perceptions of Mobile Technology Supported Peer Observation Process

When asked about their perceptions of working within mobile technology supported PLCs and being part of the peer observation process, PSTs reported the following:

1. I learnt how to successfully collaborate as a team and gained loads of exciting ideas and ways to support and encourage learning in my classroom.

In excerpt 1, the PST suggests that the process of engaging in a mobile technology supported PLC-enhanced understandings of how best to collaborate. She emphasizes that she gained new ideas about creative approaches to teaching that she may not have had had access to if taking another approach to learning.

2. I was really interested to see how others use the 5E framework and pedagogical tools in different ways. I am always really interested when people do things in ways I never thought of.

Excerpt 2 shows that the PSTs valued the opportunity to observe their peers interpreting, through teaching, the learning they had all engaged in, in University-based workshops, in a classroom with “actual” students. An implication here is that, while the PSTs have many opportunities to discuss and clarify their thinking in University workshops, the opportunity to actually see each other teach provides an insight that is not possible through discussion only.

3. Mimicking the structure of how planning is done in schools, I think this was a valuable team experience. Sharing of ideas made the unit more diverse and interesting.

The PST shares their view, in excerpt 3, that through planning and teaching within PLCs reinforced by technology supported peer observation; the process was a more authentic and faithful representation of what they believe will occur in their working life as a teacher.

4. Great opportunity to teach a sequence of lessons to students and have feedback from peers and

lecturers. Liked working collaboratively as everyone brought ideas to the table which were critically reviewed so on the whole lessons were at a high standard.

The PST reflects in excerpt 4, that the process of peer observation and feedback was a very positive experience. They share their view that the opportunity resulted in overall high-quality lessons being planned and taught. It was interesting that the process of their teaching and planning being “critically reviewed” was seen as a positive, where this could easily be perceived in a negative way.

5. I feel far more confident in the teaching of STEM units. My knowledge background was strong and I was confident I knew the concepts very well. My experiences here have now given me the ability to know how to apply my knowledge and transfer the desired understandings to my students. Scaffolding their achievement of success criteria is achieved by designing appropriate activities and lessons that are hands on, engaging, student-led, and also, highly enjoyable and fun.

The PST, in excerpt 5, suggests that while their content knowledge in the various disciplines of STEM was strong, the process of engaging within the PLC and providing and receiving feedback through peer observation strengthened their pedagogical content knowledge. This aligns with data collected, reported in the following subsection, suggesting that feedback was focused more on pedagogical approaches, than specific content in the STEM disciplines.

6. It has been the most constructive process of science teaching I have experienced in the entire Master of Teaching course. The feedback has been excellent over the course to allow us to refine and develop the lessons.

PSTs, prior to engaging in the STEM elective, had not had the opportunity to observe each other teach or provide and receive feedback from each other on their teaching. Comments from the PST in excerpt 6 indicate that this was a very useful component of the elective. PSTs have received feedback and critiques of their teaching throughout the course from University academic staff and mentor teachers, in addition to a range of anecdotal feedback. Excerpts suggest that the PSTs, at times, value the feedback from their peers as more

meaningful than from individuals who they would consider to be assessing and judging them.

PST Focusses of Peer Feedback

Table 1 shows how PSTs focused their peer feedback within Padlet. It is clear that “engineering” and “technology” was not a focus of the teaching or of feedback. This can largely be explained. As previously stated, in the year that this data was gathered, the context for teaching was “Bees and Bee Adaptations.” While subsequent and previous years of the elective involved a greater focus on these disciplines, this context did not lend itself well to exploration and investigation with engineering and technology.

Interestingly, the data shows that PSTs were by far and away most concerned with focusing their peer feedback on general pedagogical issues, providing 204 contributions with this as a focus. The next closest, mathematics, received 66 contributions.

It was of interest to observe that while only marginally, mathematics was a greater focus of PST feedback than science. Given, the scientific nature of the context of this inquiry, we had anticipated that science would be a greater focus during these discussions. Additionally, some researchers in the field of STEM education claim that mathematics can often be overshadowed when working in a STEM context (English 2015). They suggest that science can be considered the “dominant” discipline within the term. Data collected here

Empowerment and Disempowerment in Peer Observation Within Pre-service Teacher, Technology-Assisted Integrated STEM Education, Table 1 Feedback from Padlet provided by PSTs, categorized by discipline

	Group A	Group B	Group C	Total
Engineering	0	0	0	0
General pedagogy	60	51	93	204
Mathematics	37	21	8	66
Science	19	11	25	55
STEM	6	1	5	12
Technology	0	2	0	2

Empowerment and Disempowerment in Peer Observation Within Pre-service Teacher, Technology-Assisted Integrated STEM Education, Table 2 Focus of peer feedback from Padlet

	Week 1	Week 2	Week 3	Week 4
Engineering	0	0	0	0
General pedagogy	59	45	48	52
Mathematics	0	14	36	16
Science	13	19	6	17
STEM	3	1	3	5
Technology	0	0	0	2

suggests that when working to develop and teach STEM-based inquiry learning, mathematics, if anything, was of marginally greater an emphasis.

Table 2 provides insight into how PSTs’ focus of feedback changed throughout the 4-week teaching sequence. While, there were a greater number of overall mathematics-focused contributions compared to science-based contributions, no contributions were focused within the area of mathematics in Week 1. We hypothesize that the scientific context of the teaching sequence was central to “setting the scene” for the investigation. Further evidence for our hypothesis relates to science-related feedback being in greatest evidence in the initial 2 weeks of the sequence.

Conclusions and Implications

Underpinning and supporting the peer observation process was a CSCL environment (Padlet) accessed through mobile technologies. A number of features were essential for mobile technologies to support PST feedback. These included equality of contribution. All participants also had equal ability and agency to contribute through their personal device. PSTs had multiple opportunities to contribute. Unlike face to face feedback, they could build on and develop their feedback over the course of the lessons. They had the opportunity to edit and modify their own contributions making the process more fluid and dynamic. It is believed that the use of mobile technologies enhanced the metacognitive practices of the observers. In addition to having the ability to

edit their own contributions, PSTs built on other PSTs contributions, allowing them to recognize aspects of the teaching process they may not otherwise have considered.

Critics of peer observation within PLCs have argued that the process is easily subverted. They suggest that it is easily manipulated by figures of authority, as an opportunity to ensure compliance and an opportunity to carry out surveillance (Shortland 2004).

Others suggest that staff are not qualified to judge their peers. There remains no definitive agreement about what constitutes the most successful teaching style or method; therefore any judgment or critique of peers relies on the (peer) assessor’s subjective view about what constitutes effective teaching practices (Cosh 1999).

We question how, when teaching at a school or tertiary level, even when a reflective approach to peer observation and feedback is utilized, can the power imbalance between observer and observee be reconciled?

We agree with Shortland (2004) that the approach regularly taken to peer observation and feedback in professional teaching environments usually provides only a small “snapshot” of what has occurred throughout a sequence of teaching. Thus, it becomes difficult for an observer to know how the session relates to the rest of the program. With this constraint in mind, the quality and value of feedback is compromised.

Despite these reservations, we see mobile technology supported peer observation within PLCs as part of PST education and training as fundamentally different. Our PSTs are enrolled in their course with the purpose of preparing to become primary school teachers. Thus, they are positioned, upon enrolment in their course, as learners.

Survey data, collected as part of this study, indicates that rather than feeling surveilled or viewing the process as an exercise in compliance, PSTs embraced the process as an authentic learning opportunity. Relative to the potential levels of disempowerment they experience when being observed by academic supervisors and mentor teachers, the process of observing and being observed by their fellow students is liberating, in that all participants in the process are striving to

achieve the same goal; becoming the best teacher possible.

Unlike examples provided in the literature (Cosh 1999; Shortland 2004; Hammersley-Fletcher and Orsmond 2004), observers were able to view the entire teaching sequence (occurring over 4 weeks). Thus, PSTs were able to see how the sequence unfolded, avoiding issues associated with an observer having a disconnected understanding of how the teaching cohesively came together.

In addition, to gaining an understanding of how our PSTs perceived the process of technology supported peer observation within PLCs, we were interested in how our PSTs would focus the feedback that they posted in the CSCL environment (Padlet). It had been anticipated that the content focus of their feedback may predominantly lie in the area of science, as a result of literature suggesting that mathematics is often overshadowed within a STEM education context (English 2015). However, as reported, mathematics was of a slightly greater emphasis in PST contributions within the CSCL environment.

It had not been anticipated that the overwhelming majority of feedback would relate to observations and suggestions about general pedagogy. It may be that the PSTs felt more secure and confident offering feedback related to broader pedagogical issues. It is also possible that given that the teaching sequences were collaboratively planned amongst the PST cohort, there was a common understanding of the content being taught; therefore, PSTs had less need to focus feedback on content areas. In the moment, pedagogical choices, however, are not necessarily shared understandings and therefore would compel observers to provide commentary or feedback.

Interestingly, no mathematics-centered feedback occurred in the first week of data collection. We have argued that science has provided a context, or a tangible narrative, from which to “steer” the STEM sequence of learning. Therefore, it is a major focus of feedback in the initial 2 weeks.

We suggest an implication for the planning of STEM sequences of learning, or for a general framework for STEM units, that science can be

considered the “host domain,” from which engagement in the learning is launched.

Mathematics is later utilized within the STEM sequence of learning as a tool for the interrogation and analysis of data, helping to communicate understanding. Neither discipline need be overshadowed. Instead PSTs can be encouraged to achieve balance, utilizing science and mathematics in a purposeful, targeted, and synergistic manner.

E-Portfolio in Higher Education

Amjad M. Abuloum
Bahrain Teachers' College,
University of Bahrain, Zallaq, Bahrain

Introduction

The 1970s and 1980s of the twentieth century witnessed a great transformation of focus toward direct measures of writing. As a result, the portfolio was introduced as a means to examine real samples of students' writing especially in disciplines with significant writing components (Lorenzo and Itelson 2005). Therefore, a

portfolio can be seen as an exhibition of student work that provides real evidence of achievement. In fact, Linn and Gronlund (2000) used the term “student learning portfolio” to refer to the collection of examples of student work annotated with student's reflective commentary. These examples can be curricular activities, such as course assignments and projects, or cocurricular activities such as sports, music, drama, etc. By facilitating students' reflection on their own work, student learning portfolios can help students become more aware of their learning and needs.

The rapid development of Web technologies and the increased availability of Web-based platforms have introduced a huge number of e-learning tools that have greatly contributed to the improvement of teaching and learning as well as the enhancement of academic performance (Alhazmi and Rahman 2012). Electronic portfolio (or e-Portfolio) is one of these innovative e-learning tools that have proved to be of great value in monitoring students' progress and enhancing their educational outputs. According to Eynon et al. (2014), this pedagogical tool can improve student learning through recognition and synthesis of ideas, reflection, self-evaluation, self-awareness, and action planning and goal setting.

An e-Portfolio is a collection of student work constructed electronically on the Web or on any recorded media such as CDs, DVDs, Zip disks, etc. This collection, which is usually managed by the student, contains electronic evidence (called artifact) in the form of text, files, images, audio and video files, blog entries, and hyperlinks. The hyperlinks enable the student to make connections between and among classes, experiences, and observations. Being electronic makes e-Portfolios more flexible, more portable, and easier to share. It also enables students to reuse entries in different presentations and for different views and contexts. Therefore, the “e” in e-Portfolios adds more value to their use in education (Yancey 2001). While the focus of print portfolios is mostly on the course level, the focus of e-Portfolios extends to the whole curriculum as well as to outside experiences (Yancey 2009).

In a broad sense, Kunnari and Laurikainen (2017, 7) defined e-Portfolios as “student-owned digital working and learning spaces for collecting, creating, sharing, collaborating, reflecting learning and competences, as well as storing assessment and evaluation. They are platforms for students to follow and be engaged in their personal and career development, and actively interact with learning communities and different stakeholders of the learning process.” This broad and comprehensive definition makes the experience of creating and developing e-Portfolios meaningful and learning-rich for students. Belgard (2013) stated that the creation and sharing of evidence and artifacts in the e-Portfolios develop students’ collaborative skills. Moreover, the reflection involved in the creation of these e-Portfolios promotes meta-learning, which puts the students in the state of being aware of and having control over their own learning. It’s worth to mention that without this reflection, the value and richness of e-Portfolios are diminished (Ramey and Hay 2003).

According to Swan (2009), students usually upload artifacts to a Web server where they get tagged and then stored in a database. Tagging is not only essential for the storage and retrieval of the artifacts but also for the reflections and feedback that can be added to these artifacts. Students can filter and sort the artifacts to create completed portfolios for their courses or programs. This process of e-Portfolio creation and development was recognized by Danielson and Abrutyn (1997) who divided it into five stages:

1. Collection: where students learn to save artifacts that represent the success and growth in their teaching and learning
2. Selection: where students review and evaluate the artifacts and select those that best demonstrate achievement
3. Reflection: where students reflect on the artifacts as well as on the whole e-Portfolio
4. Projection: where students review their reflections on learning and set goals for the future
5. Presentation: where students share their e-Portfolios with others

Over the last decades, there has been a rapid increase in the utilization of e-Portfolios in higher education (Baris and Tosun 2013). In fact, e-Portfolios have been largely integrated into the education settings of the institutions of higher education all over the world (Hohlfeld et al. 2008; Zubizarreta 2009). Compared with other technology applications, e-Portfolios are believed to have a greater impact on higher education (Batson 2002). Trevitt et al. (2013) posited that e-Portfolios can play a crucial role in screening university graduates who are expected to demonstrate certain skills, such as higher-order thinking, communication, and collaborative abilities.

Bringing e-Portfolios into institutions of higher education is a challenging process. However, with deep motivation and determination, this process can be less challenging and more successful. Recently, Sellami (2017) conducted a case study to implement an initiative of introducing an e-Portfolio into a master’s degree program at a Tunisian university. He found out that students not only enjoyed creating their e-Portfolio, but they also realized its positive impact on their learning, career planning, knowledge acquisition, and the development of their skills. Furthermore, he concluded that the e-Portfolio encouraged self-reflection among students and helped them showcase their talents.

Benefits of E-Portfolios

The literature has documented a number of benefits of using e-Portfolios in the learning environment. These benefits include, but not limited to:

- Technology skills: By working on their e-Portfolios, students develop technology, writing, and multimedia communication skills (Bartlett 2002; Barbera 2009; Wakimoto and Lewis 2014).
- Learning through reflection: E-Portfolios allow students to evaluate their learning processes and outcomes by self-reflection and comments from others. Considered interactive platforms, these e-Portfolios can help students recognize personal strengths and weaknesses

in skill acquisition and development (Roberts et al. 2013; Sellami 2017).

- Career development: E-Portfolios make it easy to share the collection of work samples and skill demonstrations with potential employers (Reese and Levy 2009). They provide a rich source of information for employers and professional organizations (Simmons and Williams 2012; Reardon et al. 2007).
- Organizational ties: E-Portfolios can strengthen the organizational ties with students even after graduation. They can also establish connections with prospective students (Reese and Levy 2009).
- Student assessment: By providing authentic assessment, e-Portfolios can be useful in both formative and summative assessment of students (Liu et al. 2004; Reardon et al. 2004; Sellami 2017).
- Work readiness: E-Portfolios demonstrate student work readiness by providing evidence of individual growth (Basken 2008).

Types of E-Portfolios

The e-Portfolio literature has documented three main types of e-Portfolios that support different assessment purposes (Hewett 2004; Mason et al. 2004; Willis and Wilkie 2009):

- Documentation (personal developmental) e-Portfolios show the growth toward achieving specific, pre-defined learning goals. They can also be used to monitor the advancement of skills over a period of time. These e-Portfolios enable students to develop, display, and reflect on their own learning. For assessment, developmental e-Portfolios support diagnostic assessment by providing a communication channel for students and instructors to plan and check how learning is progressing.
- Assessment e-Portfolios document the phases of the learning process and reflect upon the students' journey toward mastery. They make students aware of how they learn best. This type of e-Portfolios supports self-assessment and can help instructors in their assessment

by capturing the different aspects of student learning.

- Showcase (presentation of products) e-Portfolios highlight students' accomplishments and competences. Since they include graduates' best works and products, these e-Portfolios are usually presented to potential employers in job applications. This is why sometimes they are called career e-Portfolios. It's worth to mention that this type of e-Portfolios supports summative assessment of students' competences and learning outcomes.

Challenges to the Use of E-Portfolios

As explained earlier, a huge volume of research has indicated that e-Portfolios can have a positive impact on the learning experience. In higher education, this innovative technology plays a vital role in enhancing learning, conducting assessment, meeting standards, and increasing student employability. However, this does not imply that e-Portfolios are the panacea for all diseases because there are significant challenges that may limit their effectiveness and utilization (Cheng 2008; Lee 2007).

One of the main challenges that face institutions of higher education is the time-intensive nature of the development of e-Portfolios, especially when used with large classes and groups. In a recent study, Sellami (2017) concluded that although most students appreciated the use of e-Portfolio, they found it time-consuming. He also declared that enhancing the use of e-Portfolio caused extra hours of teaching load for instructors. Therefore, students and instructors may become reluctant to the use of e-Portfolio because they expect a heavy workload.

Another serious challenge to the use e-Portfolios is related to student's development of basic critical skills, such as collecting, selecting, and reflecting on potential material. Milman (2005) emphasized that students need to learn how to select, collect, reflect, write, and respond to feedback for e-Portfolio assessment. For instance, she mentioned that selecting what to put into the e-Portfolio was difficult for both students who

had lots of evidence of student teaching (e.g., activities, papers, lesson plans, etc.) and those who had not yet experienced student teaching. According to Sharma and Mishra (2006) and Zubizarreta (2009), without a significant focus on reflection, e-Portfolios may simply become a collection of information rather than a means to support personal development and reflective learning.

Hughes (2008) addressed an important challenge related to instructors. He pointed out that the use of e-Portfolios may require instructors to change the traditional assessment practices in their courses. They should be prepared to engage with their students in meaningful individual and collaborative activities that develop comprehensive interactive cultures. They should also prepare relevant rubrics and marking guides to overcome the subjectivity of the e-Portfolio-based assessment.

The use of e-Portfolio system can be hindered by significant technical challenges. According to Peacock et al. (2010) and deFreitas and Jameson (2006), these technical challenges may include, but not limited to:

- Lack of compatibility of different e-Portfolio systems and their functionality
- Lack of availability of computers and problems with access to the Internet
- Unavailability of the e-Portfolio systems due to site maintenance and frequent updates
- Limited technical knowledge and proficiency among students and instructors
- Issues of privacy and security of data
- High initial operating costs
- Adaptability for various purposes

E-Portfolios as an Assessment Tool

Since assessment for learning plays an important role in higher education, instructors have shifted their attention from traditional standard tests to new assessment methodologies that enable students to prove their skills when solving problems, reflecting, analyzing, and synthesizing. O’Keeffe and Donnelly (2013) asserted that e-Portfolios

enhance assessment and feedback and foster creativity and, therefore, can be valid and reliable tools for learning assessment. In fact, assessment can benefit from e-Portfolios’ collection of various samples of student work since it provides a larger, more detailed view of student’s knowledge and achievements. Furthermore, according to Smolyaninova and Shilina (2011), e-Portfolios enhance objectivity of assessment by increasing the number of people involved in it and help to make instructors’ assessment more transparent. Therefore, it is essential that instructors take advantage of e-Portfolio assessment (Yilmaz and Çetinkaya 2007).

Rao et al. (2012) declared that e-Portfolios not only store achievements but also demonstrate the processes of accomplishing those achievements. This, of course, gives e-Portfolios an advantage over traditional forms of assessment (Donnelly et al. 2010; Lambert et al. 2007). In fact, e-Portfolio assessment has moved above conventional assessment to a level where student learning is deeply facilitated and enhanced. Therefore, institutions of higher education have urged students to develop e-Portfolios for the purpose of summative assessment, self-directed learning (formative assessment), and employability (Lam 2015).

Literature has witnessed a huge volume of studies that examined the use of e-Portfolio assessment to produce positive outcomes. Recently, Roberts et al. (2016) conducted a study that investigated the effect of an e-Portfolio-based learning environment on preservice teachers’ reflection abilities. Based on the findings, the researchers concluded that the e-Portfolio environment was effective in scaffolding students’ reflective thinking. The same conclusion was underlined by Montgomery (2003) and Lynch and Purnawarman (2004) who stated that e-Portfolios are important vehicles for supporting critical thinking of learners with reflective thinking actions.

The study by Gulbahar and Tinmaz (2006) showed that the use of e-Portfolios helped students to overcome their anxiety and promote their confidence. The study also showed that students liked the e-Portfolio assessment system

incorporated into their courses. In the same manner, Sellami (2017) found out that students did appreciate the fact that their evaluation was based on their e-Portfolios, rather than on their performance on classical examinations. Similarly, Akçıl and Arap (2009) concluded from their study that all students liked the use of e-Portfolio where more knowledge occurred at the end of the e-Portfolio process.

Ragusa (2010) indicated that in higher education, e-Portfolios are gaining prominence as an assessment tool. They are being used increasingly, especially in terms of demonstrating skills, abilities, and achievements against certain competencies or criteria (MacEntee and Garii 2010; von Kinsky and Oliver 2012). Furthermore, e-Portfolios not only can provide ways for students to use feedback from assessment to support their learning but can also enhance their professional activities (Kocoglu 2008). Some researchers emphasized the potential of e-Portfolios to support what's called "integrative learning," where class and work experience are integrated together and knowledge or skills are presented across various classes (Eynon 2009; Light et al. 2009).

Over the last two decades, e-Portfolios have become more common in teacher education programs at institutions of higher education as a tool for assessing preservice teachers. Carney (2004) concluded from seven case studies that e-Portfolios of preservice teachers are actually their autobiography as a teacher depicting their philosophies of education. Donaire et al. (2010) viewed e-Portfolios as a perfect follow-up tool to document students' competences development through their degree studies. Therefore, it's been deeply believed that e-Portfolios are the right tool to track the general competencies acquired by teachers, including content knowledge, knowledge of learning and learners, pedagogical skills, learning environment, assessment, instructional technology, school and community engagement, ethics, and professionalism (Anderson and DeMeulle 1998; Naizer 1997; Reis and Villaume 2002; Simmons 1996). Currently, most teacher education programs require prospective student teachers to develop and present an e-Portfolio of

evidence as part of their graduation qualifications (Groom and Maunonen-Eskelinen 2006).

Some institutions of higher education have taken the e-Portfolio assessment to a higher level where the collections of student artifacts with reflection are utilized in assessing the effectiveness of their courses, curricula, and programs (Bates 2010; Van Aalst and Chan 2007).

The implementation of e-Portfolios as an alternative assessment strategy in the institutions of higher education has been the subject of a large number of research studies. Salvia et al. (2007) and Van Wyk (2017) have put forward several suggestions for the successful integration of e-Portfolio assessment:

- Imbedding the e-Portfolio assessment in the curriculum and aligning it with the learning outcomes.
- Developing intended outcomes related to the purpose and objectives for using and implementing e-Portfolio assessment.
- Instructors need to be aware of the virtues of the inclusion of e-Portfolios as part of the work integrated learning requirement.
- Overcoming the financial needs that result from rethinking of curriculum evaluation.
- Developing clear assessment criteria for evaluating e-Portfolios. These criteria need to be clarified to students and assessors.
- Integrating the use of e-Portfolios within assessment plans.
- Encouraging cooperation among students as well as between students and their instructors.
- Designing tasks that illustrate work in the real world. Instructors need to focus on authentic problems and assignments.
- Encouraging student reflection.

Conclusions

E-Portfolios are not a new concept; they have been in use in education for more than a few decades. E-Portfolios have proven to provide richer, transformative educational experiences for students. They enable students to share information, collaborate with others to complete tasks,

and reflect critically on their work. Therefore, e-Portfolios have the capacity to become lifelong learning tools.

E-Portfolios are vital for students' development because they have the potential to be a learning tool, an assessment tool, and a record of achievement. Their great potential of assessment has gained attention among institutions of higher education.

The implementation of e-Portfolios in higher education can have a spectrum of educational values, including the increased ability of students to achieve learning outcomes, better communication between students and instructors, active participation in the classroom, development of critical thinking skills among students, making students aware of their learning, and enabling students to take control of the learning tasks.

However, e-Portfolios are not without their challenges. These technical and pedagogical challenges can limit the effectiveness of a long-term, institutional implementation of e-Portfolios. Among these challenges, the following can be mentioned: time-consuming, students' need to develop basic critical skills, changing the traditional assessment practices, and several technical challenges and issues.

Introduction

Ethical Dilemmas in Teaching

Society expects teachers to be guided by ethical principles in dealing with the bullying they encounter. Teachers are perceived as professionals who help shape the image of society and should be capable of making ethical decisions for the general good. As ethical agents, they shape coming generations of citizens (Aloni 2013; Barrett et al. 2012).

Ethical dilemmas in teaching are defined as complex situations that usually entail ethical conflicts for which teachers and educators are required to provide appropriate responses (Shapira-Lishchinsky 2013; Bullough 2011).

Studies indicate that dealing with ethical dilemmas helps educators to develop emotionally, morally, and operatively. *Emotionally*, dealing with ethical dilemmas emerges teachers' feelings of empathy and solidarity, recognition of others' feelings and emotional and existential state, as well as concern for assuring their dignity and welfare (Aloni 2006, 2013). *Morally*, by engaging in such dilemmas, teachers elevate the importance of basic human values and egalitarianism. It also encourages moral judgment based on concepts of universal human rights. It stimulates rational thinking, autonomy, neutrality, and consistency. In addition, by dealing with ethical dilemmas, individuals strive internally to adhere to a moral stance in the face of temptations and obstacles, whether internal or external (Aloni 2006, 2013; Cohen 2015; Shapira-Lishchinsky 2013).

Operatively, studies show that familiarity with a variety of ethical dilemmas and of ethical principles assists teachers in constructing a professional toolbox. Analyzing cases and mapping their component parts and proposing several possible options for actions provide teachers with tools that they can use when facing similar situations in the future. More generally, dealing with ethical dilemmas helps members of an organization to find a common ground and to create unanimity of ideas about the basic human values that guide them as a professional group (Aloni 2006; Davidoff 2016; Gevton 2011; Shapira-Lishchinsky 2013, 2016).

Teachers confronted with ethical dilemmas related to bullying at school feel powerless and unsupported by the education system (Dedousis-Wallace et al. 2014; Gaikhorst et al. 2014; Shapira-Lishchinsky 2013). Various studies show that most teachers complete their training without any reference to bullying being one of their key professional difficulties. They feel a need for operational experience-based training, in a protected, cooperative environment, that will enable them to acquire operative skills to deal with bullying in school (Lindqvist et al. 2017; Sela-Shayovitz 2009).

This article proposes the use of team-based simulations (TBS) (role-playing) and video-based reflections to train teacher trainees to deal with ethical dilemmas related to school bullying. School bullying is a widespread, global phenomenon that disrupts educational activity (CDC 2017; Fishman 2015). Two recent studies, one sponsored by the United Nations (UNESCO 2017) and the other by the World Health Organization (WHO 2016), revealed the extent of conflicts and bullying in schools. According to the 2016 UN research, 29–46% of school-age children worldwide suffer from bullying on a regular basis (UNESCO 2017). The WHO (2016) research, which relates to OECD countries, found that 33% of the students reported having been victims of bullying or harassment at various levels of power at least once in the past 2 months and 14.7% of the students reported various attacks on school premises (CDC 2017). The problem attracts much public, social, and academic attention, and globally it is considered a key problem in societies that see school as agents of socialization (CDC 2017; Harel-Fisch et al. 2011).

The use of simulations promotes a sense of psychological empowerment in coping with ethical dilemmas in school, and it encourages cooperation and reflective group thinking in a pleasurable and experiential environment of learning that motivates the learning experience (Davidoff 2016; Shapira-Lishchinsky 2014; Walter and Adam 2014). Another important aspect is the use of video as part of the reflective process during the simulations that enhance deeper understanding of critical situations. Watching extracts from filmed simulations in reflective team discussions helps participants to gain insights of verbal and nonverbal messages such as tone of voice and body language. It also enables the participants to evaluate and analyze their own responses and behaviors. It promotes their understanding of the impact of their behaviors and decisions (Davidoff 2016; Harford and MacRuairc 2008; Masats and Dooly 2011; Shapira-Lishchinsky 2016).

Moreover, the focus of this article on simulations is based on previous studies which indicate that the use of simulations leads to an applicative transfer of operative memory structures in the brain (Bar 2011; Kwanghyun and Soyeon 2016). These operative experiences acquired through simulation stay in the learners' brain as a real-life experience. Furthermore, the simulations make it possible to predict and later on to use strategies in real life that were internalized in similar cases encountered previously during simulations (Bar 2011; Kwanghyun and Soyeon 2016).

School Bullying and Its Consequences

"Bullying" refers to any form of attack with or without the use of physical force. It includes "violence," which refers to acts that include the use of physical force and is only one of the many forms of bullying (Fishman 2015). School bullying can be defined as follows: directed behavior intended to emotionally or physically harm other people, their property, or school property (Cornell and Limber 2015). Students who are bullied experience feelings of anxiety, lack of protection, dissatisfaction with life, and high levels of depression, including suicidal thoughts. These facts are stated to turn school bullying into a problem that threatens the education system (Bonanno and Hymel 2010; Burger et al. 2015; CDC 2017).

Bullying Prevention Program for Educators

Research indicates that most educators are extremely disappointed by lack of attention bullying receives in teacher training curricula. Bullying is seen as being a low-priority issue when compared to teaching theoretical content and learning academic teaching-learning strategies (Gaikhorst et al. 2014; Sela-Shayovitz 2009; Shavit and Blank 2010). Studies have shown that educators have a need to practice and

apply alternative methods of coping with bullying in a supportive environment. These include opportunities for sharing experiences, ideas, and opinions about ethical challenges they encounter (Shapira-Lishchinsky 2013; Gaikhorst et al. 2014). Previous studies emphasize the importance of workshops as a means of preparing teacher trainees for dealing with bullying hyphenated ethical dilemmas in a practical and protected way that reflects their daily needs as professional teachers (Sela-Shayovitz, 2009).

Ethical Dilemmas in Dealing with Bullying

Ethical dilemmas in bullying are described as complex situations that usually entail ethical conflicts. Educators are required to provide appropriate responses to such dilemmas (Poliner Shapiro and Stefkovich 2016) and are expected to work according to ethical principles to be able to make ethical decisions while dealing with school bullying (Bullough 2011).

Studies indicate that challenging educators with ethical dilemmas helps them acquire knowledge and skills to deal with them effectively (Aloni 2013; Barrett et al. 2012; Gevton 2011; Poliner Shapiro and Stefkovich 2016). From a moral perspective, engaging in ethical dilemmas as part of their training enhances educators' egalitarianism and moral judgment. From an operative perspective, engaging with these ethical dilemmas assists educators in developing skills that help them create consensus around ideas about basic human values (Aloni 2006; Shapira-Lishchinsky 2013).

Studies show that teacher trainees feel professionally inadequate and powerless when dealing with ethical dilemmas related to bullying scenarios and that they have limited means of action. Hence, they feel uncertainty (Lindqvist et al. 2017; Sela-Shayovitz 2009). In resolving ethical dilemmas and professional inadequacy, trainees tend to depend on colleagues to help them deal with bullying (Sela-Shayovitz 2009).

Meta-cognitive Thinking in Dealing with Bullying

“Meta-cognitive” refers to the individual’s ability to think about his/her thinking, to plan and navigate his/her own cognitive processes, and to make informed decisions (Flavell 1970). Behaving in this way, educators are perceived not only as thinking individuals but also as self-regulators capable of assessing and directing themselves to specific behaviors. Meta-cognitive strategies include the active development of thinking skills such as structuring and integrating new information with existing information, planning, assessing progress, and improving performance by self-check and assessment (Flavell 1979). These strategies assist learners to cope with and analyze ethical dilemmas involving bullying (Jenkins 2012).

Previous studies indicate that reflective and meta-cognitive thinking can significantly affect the treatment and prevention of bullying in school (Burger et al. 2015; Strohmeier et al. 2012). These studies noted that professionals are more likely to make quality ethical decisions when they are participating in a meta-cognitive process (Christensen and Kohls 2008). Engaging in team-based reflective discussions and meta-cognitive thinking processes helps educators to improve their pedagogical approach to bullying-related ethical dilemmas. Educators who engage in such processes manifest rich theoretical knowledge and investigative-critical thinking. Furthermore, when dealing with bullying-related ethical dilemmas, these educators display fewer fears about their professional position and greater feelings of professional autonomy as well as ethical commitment to their work and to their teaching colleagues (Burger et al. 2015; Shapira-Lishchinsky 2013; Strohmeier et al. 2012).

Training by Team-Based Simulations

Simulation is defined as a model of reality that includes elements of role-playing (Walter and

Adam 2014). Simulations provide learners with the opportunity to “step into the shoes” of figures involved in the situations under discussion. When faced with similar events in real life, individuals can extract subconscious behaviors learned from these simulations (Bar 2011; Kwanghyun and Soyeon 2016). Simulations encourage collaboration as well as reflective thinking through investigating ethical dilemmas by role-playing (Anderson and Lawton 2009; Clark 2007; Walter and Adam 2014).

Previous studies indicate that when a person predicts behavior in a given situation and develops his future episodic thoughts, he needs an earlier acquaintance with the subject (Atance and Hanson 2011; Barsalou 2009). It was found that when simulations are used, a physiological (sensory, visual, auditory) memory of the situation is created. This memory improves the ability to assimilate action strategies based on reflective thinking for future use. In fact, as these strategies are applied in the memory, they become available and easier to retrieve in reality events (Atance and Hanson 2011; Barsalou 2009; Liberman et al. 2011).

According to Bar (2011), the person retrieves the information he stored in his memory, similar to the kind stored in a script library. These operational memories neutralize the disturbance of surprise that causes restlessness and contribute to the development of the person’s emotional, cognitive, and operational abilities (Barsalou 2009; Panichello et al. 2013). Through simulation, educators develop a sense of mutual assistance, which increases their self-confidence as well as their willingness to expose their difficulties and weaknesses to other team members (Shapira-Lishchinsky 2013).

Studies supporting the use of video during simulation workshops suggest that learning not only occurs during role-playing but also continues and deepens during the investigative stage. In this second stage, the participants analyze the events by watching role-playing videos and discussing a range of solutions before making a decision. Previous studies have indicated that the use of video improves practical thinking about

pedagogical strategies and increases participants' psychological empowerment (Davidoff 2016; Harford and MacRuaric 2008; Masats and Dooly 2011; Shapira-Lishchinsky 2016).

Psychological Empowerment and School Bullying

Psychological empowerment is defined as "intrinsic motivation reflecting a sense of self-control in relation to one's work and an active involvement with one's work role" (Seibert et al. 2011, p. 981). Psychological empowerment is composed of four cognitions: significance, self-definition, ability, and influence. Psychological empowerment in performing tasks is the relationship between individuals' beliefs, values, and standards and their professional functioning. Since the 1980s, interest has been growing in psychological empowerment in the context of motivation, quality of decision hyphenated, and task performance and in terms of its effect on the ability to cooperate effectively in team processes in a manner that contributes to personal and organizational growth (Kwanghyun and Soyeon 2016; Seibert et al. 2011).

Empowerment in school is characterized by assuming responsibility leading to professional growth. Teachers with high psychological empowerment tend to feel that they have the skills and knowledge necessary to improve their actions and solve problems effectively. Generally, they see themselves as personally efficacious, free to make decisions, influential in terms of applying strategies, and empowered by the organization to introduce change. Research has also shown a positive correlation between teachers' psychological empowerment and their commitment and performance while dealing with student bullying (Avidav-Unger et al. 2011; Chen and Chen 2008; Kwanghyun and Soyeon 2016; Sprietzer 1995).

Among teacher trainees, high levels of psychological empowerment may encourage educators' teaching efforts, their willingness to adopt new approaches to increase their students' learning,

and their level of perseverance when faced with obstacles (Hungafu 2012). In addition, a study among 90 teacher trainees, which compared the use of simulations to train teacher trainees to deal with ethical dilemmas in cases of school bullying, indicated that the use of group simulations, combined with reflective discussions, contributed significantly to the trainees' psychological empowerment (Davidoff 2016). According to this study, students who used simulations as part of group reflective discussions had a significant increase in their "self-confidence and sense of control" and their "capability of making rational decisions" (two aspects of psychological empowerment). Furthermore, the group who used simulations created an extensive variety of possible solutions for the ethical dilemmas, better team cooperation, and a higher propensity to promote empathy and openness in confronting complex ethical challenges. These findings are consistent with other research (Darling-Hammond et al. 2009; Hungafu 2012; Sprietzer 1995) that argue that active learning (such as role-playing) enhances teachers' capability to deal with ethical dilemmas in daily functioning. Thus, participants gain greater self-confidence, feelings of control in their decision-making, and empathy.

Various factors have been shown to enhance educators' self-empowerment: a climate of sharing and inclusion, teamwork, and active decision-making pertaining to their work (Kwanghyun and Soyeon 2016; Shapira-Lishchinsky 2014; Sprietzer 1995). Research also shows that psychological empowerment in schools enables educators to take more educational initiatives and improve their ability to cope with difficulties and ethical dilemmas in school.

In the context of dealing with bullying at school, it is important for schools to open the door and take notice of educators' need to learn in an experiential and reflective way, of the kind suggested by the use of simulations. These schools will enjoy committed and psychologically empowered educators, more able to cope with the difficulties that are part of their daily life around bullying.

Contributions of Team-Based Simulations

A deep insight into research confirms the benefits of conducting simulation workshops combining reflective meta-cognitive discussions. Team-based simulations will enhance teachers psychological empowerment to deal with bullying. According to research, the use of simulations contributes to the psychological empowerment of teacher trainees in terms of their self-confidence and decision-making in real bullying situations (Davidoff 2016). Empowered teachers tend to view themselves as characterized by personal efficiency, freedom to make decisions, and strategic-applied influence and with a sense of capability to effect change. Simulations also help reduce teachers' feelings of helplessness in various bullying situations encountered in their work (Davidoff 2016).

Additional benefit for dealing with bullying is that educators are more likely to get a better understanding of the needs of all parties involved. It leads them to an egalitarian way of thinking and to a wide view of problems and solutions (Aloni 2013). Moreover, simulations enhance educators' abilities to predict the effects of different behaviors and responses in conflict situations (Kwanghyun and Soyeon 2016). While participating in simulations, educators experience situations similar to those they are likely to experience in the future. This enables them to manage future thinking and planning processes by creating predictive processes in their brain (Bar 2011). Additionally, simulations contribute to teachers' decision-making while dealing with conflict situations. Simulations enhance teachers' creativity and quality of decisions and actions. According to neuroscience studies, simulations contribute to the development of the frontal cortex, which is responsible for the ability to make effective decisions related to social situations and to make more developed and applied decisions, rather than decisions made in the same context without simulations (Bar 2011). In dealing with bullying, it was found that role-playing for bullying cases tends to encourage a wider range of creative ideas and empathy toward students and

colleagues (Davidoff 2016). The key benefit of the use of team-based simulations in educating teachers to deal with school bullying is summarized in Fig. 1.

To summarize, this article focused on the effects of team-based simulations, incorporated in meta-cognitive reflective discussions of teacher trainees to deal with school bullying. We focused on trainees' psychological empowerment and their ability to develop evaluation as well as solutions to ethical cases around this concerning problem.

Even though school bullying is a worldwide problem, most teacher trainees do not participate in bullying prevention training programs. This situation creates frustration and feelings of helplessness. Thus, this article suggests that from research findings, simulation is an effective way of educating teacher trainees to deal with ethical dilemmas related to school bullying. Moreover, simulations and reflective discussions contribute to the assimilation of possible solutions for ethical dilemmas faced by teacher trainees. These solutions remain in the participants' subconscious memory and can be used daily in their capacity as teachers. Furthermore, the simulations, which take place in a supportive and risk-free environment, offer a method for learning that is experiential and enjoyable.

Future Research

It is recommended by research that future studies examine how simulations for teacher trainees affect school students over time, as well as the level of bullying in school. Also, in order to learn more broadly about the effects of simulations on learning, it is recommended to extend the use of simulations to different populations (e.g., high schools/special education) and other disciplines (e.g., engineering students/entrepreneurs). Expanding the research around the use of simulations in different disciplines is extremely important since according to previous studies (Arias et al. 2018), there is a growing need for students in different disciplines to include experiential learning in their qualification processes.

Ethics and Learning for Teacher Trainees, Team-Based Simulations in Cases of Bullying in School, Fig. 1 Key contributions of team-based simulations

This need is expressed in universities in order to better prepare students from different disciplines to deal with ethical dilemmas and challenges they are likely to encounter in their professional and personal lives.

Introduction

The use of Information and Communication Technologies (ICT) in the context of writing is increasingly natural, and as a result, this interaction has caused changes in the nature and contexts of communicational processes (interpersonal, virtual, digital, and textual). This use of ICT has also changed the writing process making it more diverse and integrating with new writing formats (e.g., linear, multimodal), which may occur in different contexts (e.g., synchronous or asynchronous, individual, collective, or collaborative), and enforces the integration of digital literacy by the school (Lacina and Griffith 2012).

The integration of technologies in the classroom context is a necessity and a potential for the learning processes involving several teachers and students, with different characteristics, knowledge, and experiences. Although tools that can aid in the learning processes are well-known, there are many questions about how best to integrate these resources into classroom learning and how to manage individual differences (MacArthur 2009).

Primary school classrooms are filled with diversity that constantly challenges the teacher's role as facilitator and enabler in the process of developing children's writing skills. However, many teachers feel unable to help their students overcome their writing problems and feel that students tend not to like this type of activity (Araújo 2017). Reasons for these difficulties highlight the lack of training, time, or skills to respond to the current needs of children's literacy (Cruz 2009), who must write both in the analog and digital context. However, there is a strong relationship between ICT and schools or vocational writing (Tavares and Barbeiro 2011). Besides, there is a strong relationship in the uses of ICT in education (MacArthur 2009).

Unfortunately, many students struggle with writing problems because writing is a demanding, slow, and complex process. Students need time to understand the writing process, including writing conventions. Teachers also need to use explicit teaching practices and promote supported writing time. However, sometimes, teachers do not provide adequate responses to their students' difficulties.

In the classroom writing learning process, some students continue to present a resistance to writing. Students' "failures" are often excessively focused on mistakes (e.g., incorrectly spelled words and need for their correction) to determine their progress, as well as an overvaluation of their written products concerning the writing process. These aspects compromise how the child comprehends his/her effectiveness in the writing tasks which may lead to the creation of resistance to these types of activities that compromise not only students' individual expression but also their ability to interpret the world around them.

Writing currently implies understanding both linear and multimodal writing and involves in-depth knowledge of the various contexts and situations of written communication, including the use of technologies. In a semiotic and multi-literacy perspective (Cope and Kalantzis 2000), writing assumes a multidimensional and dynamic nature that integrates the use of linguistic, visual, spatial, gestural, and audio characteristics, as well as the role of design (in production

and presentation), in the construction of textual meaning.

Children are receptive to the use of technologies in their lives, showing personal interest to explore these resources. A clear example of this situation arose in the school year 2015/2016 when 4th grade students of clusters of schools in the city of Braga (Portugal) answered that their jobs in the future will be YouTubers, some of whom had already started the process of publishing videos with the aid of their parents. Examples like these arise in various parts of the world (Araújo 2017). However, teachers do not always integrate the use of technologies in their classroom practices or think of new ways to promote meaningful and attractive learning techniques for children using technology, largely due to the lack of time, resources, and knowledge that makes them practical and simple to implement. Despite several constraints that may arise in the use of technologies in the classroom, the integration of these resources proves to be relevant since technologies are a powerful, interesting, and flexible tool, for example, to promote authentic and interesting writing tasks.

The promotion and improvement of students' writing performance and the early intervention of classroom writing problems are very important for students' lives, allowing them to be better able to interpret the messages around them and express themselves appropriately to others. The use of self-regulated strategies, combined with technologies in the classroom context, could also help students who struggle with writing to improve their performance.

In this sense, we will explore, throughout this entry, examples of how technological resources were integrated in 4th year classrooms in the city of Braga, Portugal, to promote the improvement of the writing performance of opinion essays, which proved to be effective for most students.

Self-Regulation and the SRSD Model in Learning Processes

Self-regulation is one of the most important capacities for human beings, allowing the body

and the different organs to manage the resources according to the needs, such as the maintenance of body temperature. The human body is prepared to perform regulation processes automatically; however when there is a failure in these processes, the body goes into imbalance which may have several negative effects.

Contrary to our body, the skill to self-regulate is not innate, and we need training, effort, and cognitive maturity to develop this ability and which can also be detrimental to our existence. We also need to learn how to control our behavior, emotions, and thinking in order to obtain our goals. This skill helps us to understanding what must be done to reach our goals and continuously assess how close or far we are to reaching that goal. Teachers can help their students to progressively improve their capacities to use self-regulation in order to achieve their personal or academic goals, for example, by improving their performance in writing opinion essays. Given the potentials of using self-regulation, students should begin to develop this competency in primary school.

Therefore, the SRSD model is the strongest intervention in writing based on scientific and practical evidence that uses self-regulation to promote students' improvement in writing capabilities, with recourse to goal setting and adjustments, self-instructions, self-monitoring, self-reinforcement, and metacognition. This explicit and flexible model includes six stages: (1) develop it; (2) discuss it; (3) model it; (4) memorize it; (5) support it; and (6) independence (Harris et al. 2008). The effects of this model on students have already been tested in different countries and in different contexts (e.g., large group, small group, or individual) and reveal very positive effects on the level of knowledge and attitudes in the writing process (e.g., motivation), perceptions of self-efficacy, and writing performance (presence of several writing elements for each type of essay, improvements in writing quality, use of linking words, and, often, improving the length of essays).

However, researchers have recognized that more and different research is needed, especially in the classroom context (Graham and Harris

2013). It should also be noted that the success of the implementation of evidence-based practice as is the case of the SRSD model is not guaranteed, although it is more likely to be successful, as it will largely depend on how it is implemented and the contexts in which it is implemented. For more information on the SRSD model see, for example, <http://www.thinksrsd.com/> or Harris et al. (2008).

Technology in the Writing Process

Several authors consider that the use of ICT during the writing process can be favorable to the quality of the text produced. In this way, during the planning process, the writer uses memory and/or external resources (e.g., research, observation, rewriting) to formulate ideas that can be integrated into the text and subsequently selected and organized. Also, the mobilization of strategies in the use of the broker spelling for text editing and the possibility of correcting errors without registration in the final version can be facilitated in the accomplishment of students' and teachers' goals during the textualization process (involving the transformation and development of ideas planned in the text) and the revision process (e.g., orthographic, syntactic, morphological correction, adjustment to the objectives). Finally, regarding publishing, it allows sharing on the Internet, with the increase of author-reader interaction or the possibility of network writing communities (e.g., collaborative and interactive).

The potentialities of the graphical possibilities of formation and production of the text (e.g., emoticons, multimedia, hypertext, multimodality), as well as allowing retroversion of actions, aid in the development of confidence creating conditions for the student to see the results (MacArthur 2009; Tavares and Barbeiro 2011). Also, students can "experiment" on the computer without leaving this *mark of error*, thus enabling the stimulation of learning experiences and technological fluency.

Investigations regarding the potentiality and relevance of the use of technological tools in writing have focused on the use of the word processor associated with the keyboard or the

spelling checker, as well as speech-to-text or text-to-speech software, especially in an individual context or in a small group (Thompson et al. 2016). Some of the scientific evidence of the support technologies used by students with learning difficulties at the writing level were the orthographic corrector, speech synthesizer (programs where speaking and writing software converted speech into text), text-to-speech systems (automatic speech recognition system that converts text to speech, using artificial speech) and the predictor of words (software that predicts the correct spelling of a word, as the writer types, taking into account the frequency and context of the words) (Peterson-Karlan 2011).

Therefore, the results confirm the benefits of the use of assistive technologies for the writing process of students with learning disabilities in writing, in terms of spelling, grammar, prewriting activities, and the delineation of ideas. The use of speech synthesizers or text recognizers is particularly useful for transcription and proofreading; however, these types of tools may not be suitable for activities in the classroom context because the program is not always able to read correctly what is written, which may be counterproductive to the learning/teaching process, or there is too much noise which can condition the correct writing of words by the software (Thompson et al. 2016).

Additionally, the use of web resources is beneficial in the writing process, since it facilitates immediate access to information, exploration of individual interests and/or clarification of real-time doubts, and stimulation of the exploration of diverse communicative spaces and acts as a stimulus to peer collaboration. Consequently, these are considered some of the advantages pointed out in the use of ICT resources, although it is also recognized that there exists some difficulty in analyzing, selecting, and treating the information collected. Also, the multimedia resources have allowed access to multiple forms of communication (e.g., text, sound, and image).

The applications of notepad and Smart pens have the potentials to help students with writing difficulties to compensate for the poor ability to take notes (e.g., reduced writing fluency, difficulty in selecting meaningful information, or difficulty

in understanding the meaning of notes after reading) which results in the difficulties experienced in the processing of information. Also, other features like the digital book and digital mind maps can ease the writing process of students (Araújo 2017; Tavares and Barbeiro 2011; Thompson et al. 2016).

As for multimodal writing, it was possible to verify the potentials of the multimodal use of technologies by supporting the development and modeling of strategies throughout the various stages of the writing process, namely, with writing, editing, and revision tools. For example, the capabilities of the word processor are far superior to that of paper and pencil, easy to understand and use, and allows for the adoption of text-to-speech applications that permit the reading aloud of essays written by students, as well as the use of the spelling checker or dictionary (Cuban 2001). In another study (Wolf et al. 2016), it was also found that the use of a multimodal intervention in writing (auditory, visual, tactile, and motor) proved to be more effective than manual writing, presenting better recognition of spelling errors in dictation.

Finally, several authors have reinforced the importance of studying the instructional design of using technologies to support instructions in writing, not forgetting that basic writing skills are also important (e.g., MacArthur 2009; Troia et al. 2012).

Classroom Intervention Using Technologies

Technologies are prevalent in society, both in and out of school (Graham and Hall 2016). The use of technologies in classroom interventions has demonstrated positive effects on the learning process and writing performance, as well as the students' learning process in general (Graham and Hall 2016; Morphy and Graham 2012). For its part, learning should promote the development of functional, critical, and active literacy skills with technologies (Buckingham 2007). Similarly, students with higher ICT skills will be more prepared for the future. It is also well-known that when

students control their learning, that is, they regulate technology, they produce better results than when it is the teacher who performs this role (Hattie 2009).

In this sense, the following presents some aspects considered relevant in the planning of writing activities in the context of the classroom, using ICT.

ICT Tools in the Classroom

Current technologies consist of powerful, interactive, and flexible tools for teaching and completing quality writing by students with and without specific learning difficulties (MacArthur 2009).

The use of spelling software, speech recognition, voice synthesizers, and word predictors can be beneficial to students' writing, especially those with learning disabilities (Thompson et al. 2016). The positive correlation between computer composition and quality, and extension and motivation for writing were also verified in some studies (Peterson and McClay 2012).

On the other hand, notepad applications and smart pens have the potential to assist students who have poor note-taking skills, increasing the accuracy and comprehension of the information read (Berninger et al. 2015). Also, the use of conceptual maps or graphic organizers has had positive effects in writing on students with learning disabilities and attention problems (e.g., *Coggle*, *Mindomo*, *iMindMap*). Similarly, the use of iPads among children aged 3 to 13 during the process of alphabetization or preliteracy was considered positive in increasing motivation and concentration and in the construction of rich environments in communication and collaborative interaction (Flewitt et al. 2014).

However, we cannot forget that, generally, the use of technologies is optional, as there are contexts such as the use of assistive technologies that, by themselves, overcome barriers imposed on learning and develop compensatory strategies (CAST 2011) and which should not be ignored or underestimated. Furthermore, the potentials of writing technologies, especially among students with writing problems or with learning disabilities, are also recognized (Thompson et al. 2016), but there are different perceptions and

discourses about school and sometimes contradictory technologies (Tavares and Barbeiro 2011). As a result, there is still a great deal of disorientation in how to implement classroom interventions that respect all students and take advantage of the potentials of these resources.

Approaches to ICT Use in the Classroom

Studies involving the use of technologies in primary school classrooms have found that teachers tend to use two distinct approaches: demonstration and practice and instruction (Akbiyik and Seferoglu 2012). However, several authors highlight the importance of providing instruction and individualized assistance in writing systematically (e.g., Graham et al. 2012). Thus, several authors advocate learning spaces, with planned practices, which include the use of multimedia and technology, which offer interesting, authentic, and purposeful writing tasks (Kellogg 2008). MacArthur (2009) points out that the most important thing is to study the instructional design of using technologies to support instruction in writing while not forgetting that basic writing skills are also important. This idea is also reinforced by other authors (e.g., Troia et al. 2012). Also, Smedt and Keer (2014) consider that ICT should be combined with instruction and collaborative practices to improve students' writing. Finally, pedagogical practices should follow clear, explicit, practical, scientifically validated, and teacher-guided instructions according to the individual needs of the students in the class and the goals to be attained (Boyle et al. 2015). However, more and better research on how technologies can be beneficial to students is needed, especially among students with learning disabilities, and involving the use of mobile devices (Berninger et al. 2015).

Context Knowledge for Classroom Intervention Using Technologies

The individual characteristics of students can positively or negatively influence the effectiveness of the use of technologies in the learning process of writing (Araújo 2017; MacArthur 2009) since the use of technologies alone does not guarantee a positive effect of these tools in the education process. One factor that may be determinant is

gender since it is known that male and female students tend to present different attitudes toward writing using technologies (Araújo 2017). Also, the presence of writing problems reveals that students present lower perceptions of self-efficacy and knowledge in writing and tend to present distorted perceptions of their writing abilities, considering them to be more positive than their real performance (Araújo 2017). Similarly, the writing practices of students in the classroom, with or without the experience of the use of technological resources, are important to understand the teachers' practice of using the technologies in the classroom (Araújo 2017; Culter and Graham 2008).

Knowledge, Attitudes, and Self-Efficacy in Writing with and Without Technologies

According to the research, the students tend to present, in general, perceptions about moderate writing knowledge but lower than the perceptions regarding their knowledge in writing using technologies (Araújo 2017). However, these aspects are not always considered in the design of interventions, although positive attitudes are related to greater commitment, involvement, and effort in the writing process (Tavares and Barbeiro 2011). In this context, it was found, for example, that in a descriptive study with students and teachers of the 4th year of schooling, the students' attitudes toward writing using technologies were more positive than attitudes to writing without technologies. Also, regarding students' perceptions of self-efficacy in writing, reduced values for writing without using technologies were observed, as well as using technologies, although with slightly more positive teacher perceptions of the use of technologies by students at home, focusing on the use of games, completing exercises, visualizing videos, and conducting research (Araújo 2017).

Motivation

Research has shown that motivation is a fundamental factor in the development of learning and, consequently, the quality of students' performance assuming themselves as powerful and interactive tools. In this entry, the motivational role of ICT in writing has been widely discussed by several researchers, but the truth of this

premise is not unanimous, and there is a need for further research on this subject (MacArthur 2009; Peterson-Karlan 2011; Troia et al. 2012). Despite this, it is important to mention that many researchers reinforce the presence of intrinsic and extrinsic (e.g., social) motivation to use these tools in the writing process (Lacina and Griffith 2012).

The Role of the SRSD and Technology in the Primary School Classroom Context

The operation of writing activities using self-regulated strategy development, and the use of technologies in a self-regulated way in the primary school classroom context to promote the improvement of the writing quality of students in the 4th grade, implies a reflection on how they could be integrated (e.g., writing goals, authentic writing contexts, dictation of students' texts, writing-reading relationships), together with ICT tools and resources, for the learning of writing (e.g., word processor, spelling checker, mental maps, speech synthesizers, and others) in the activities developed in a large group and in the school context. By applying the analysis and reflection of different theoretical perspectives on how to integrate technologies in this context, and based on research in scientific databases, we proceeded with the adaptation of the SRSD model, with the integration of technologies, and the exploration of linear and multimodal writing, in a preventive intervention context for writing problems (Araújo 2017; Fuchs et al. 2008).

The structural basis of the SRSD + ICT intervention was followed by the instructional design of the SRSD model, respecting all its principles, stages, and characteristics. It was then decided to opt for the sequential exploration of the teaching of analogical, linear writing, followed by the writing of texts in digital context, the use of associated tools, and later the exploration of multimodal writing. During the process, we explored aspects such as reading, writing, and comprehension of texts or image (e.g., identifying important issues, locating information, critically evaluating the usefulness of such information, synthesizing information to answer such questions) or social skills

of interaction, collaboration, and sharing (e.g., communicating the message and/or responses to other people).

Although digital technologies and contexts had been applied during writing activities, students were expected to explain and meaningfully explore different forms, contexts, and writing tools so that through their experiences, they were progressively able to select those resources that they considered useful for their writing process (see Fig. 1).

The SRSD + ICT model was constructed taking into account some aspects such as multi-based theories, highlighting some models that contributed to the construction of the design of this intervention, specifically:

- (a) All the principles, characteristics, and stages of the SRSD model (Harris et al. 2008).
- (b) Recourse to the different stages of the Revised Blooms' Taxonomy (Anderson and Krathwohl 2001), progressively increasing the complexity of the processes mobilized for the writing activities from the remembering to creating.
- (c) The use of the TPACK model (Graham 2011) which reinforces the need for the teacher to have knowledge about writing, the use of technologies and tools which can enhance the development of writing skills and also pedagogical knowledge on how to develop these types of activities with students

(e.g., in-depth knowledge of the writing process, teaching writing strategies, and methodologies, knowledge of useful tools and contexts and enhancers of writing activities, exploration of the various forms and contexts of writing).

- (d) The use of some elements of the UDL model (Rose and Meyer 2002) with the exploration of the meaning diversity of the writing process; the exploration of multiple means of representations (e.g., auditory, visual, kinesthetic), effort, reinforcement, and persistence during the proposed tasks; and finally the role of self-regulation, interest, and ICT tools in the writing process.

Another aspect considered for the planning of interventions using the SRSD + ICT model, involving the use of technologies and digital media, necessarily implies having previous knowledge of the contexts and actors involved in the pedagogical activities of writing in the classroom. This knowledge implies understanding the knowledge, attitudes, and self-efficacy of students and teachers for writing texts, with and without the use of technologies, as well as knowledge of the use of technology and writing in and out of the classroom.

The SRSD + ICT also integrates aspects such as the involvement of evidence-based practices during the intervention in order to promote the development of functional, critical, and active

Exploratory Study Using Self-Regulated Self-Development (SRSD) and Technology in the Context of the Classroom,

Fig. 1 Aspects of the SRSD+ ICT model

skills of writing with and without the technologies that allow early detection and intervention in student's writing problems and seeks to adjust the activities to the individual and group characteristics of the class.

The inclusion of the use of ICT tools, throughout the implementation in the process, follows these steps: (a) the presentation of tools and some of the potentialities for writing, (b) discussion with students, and (c) modeling the use of tools in text production.

In this way, this research endeavored to analyze the impact of the SRSD + ICT model on students' opinion essay writing performance, through the inclusion and exploration of how and when students could or should use ICT during the writing process, and the promotion of innovative learning practices with technologies (Figs. 2 and 3).

Example of Primary Classroom Intervention with Technologies

As an example, an exploratory study that sought to analyze the impact of this intervention (SRSD + ICT) in 82 4th grade students' performance of

writing opinion essays, after 12 weeks of instruction (90 min/week) in Braga, Portugal, verified that positive results occurred in students' opinion essay writing performance, quality, essay length, and number of linking words (Fig. 4).

The effect size of the intervention was $d = 2.97$ in writing elements, $d = 3.55$ in quality of text, $d = 0.27$ in length of text, and $d = 2$ in number of linking words. The results also reinforced the positive effects of ICT in students' writing process, already evidenced in previous studies (for more information, please see Araújo 2017).

The fact that the SRSD + ICT intervention model presented here has obtained even more positive results than those previously observed with the SRSD model, which is considered the strongest model in writing intervention, as well as the use of evidence-based practices for writing combined with self-regulating ICT use in the writing process, underlines the importance of discussing how ICT can contribute to supporting students' writing learning. It also analyzes how the SRSD model with ICT can be a positive factor in improving students' writing performance, reintegrating the importance of the transversal use of a self-regulated process to the

Exploratory Study Using Self-Regulated Self-Development (SRSD) and Technology in the Context of the Classroom, Fig. 2 Examples of the writing process

different learning contexts. As a result, the role of this model with respect to individual students' needs is also highlighted.

However, although it is impossible to understand which elements contributed the most to the results, we found that the students improved their performance in writing essays through the described processes, stages, and moments of

evaluation. The progressive, explicit, flexible, and accompanied exploration process allowed students to understand and progressively apply the strategies learned, by mobilizing them during their text production processes, either collaboratively or in groups. The exploration of different forms, formats, and resources seems to have provided students with moments of reflection about

Exploratory Study Using Self-Regulated Self-Development (SRSD) and Technology in the Context of the Classroom, Fig. 3 Examples of applied resources

Exploratory Study Using Self-Regulated Self-Development (SRSD) and Technology in the Context of the Classroom, Fig. 4 Examples of the writing tasks produced by students

the various stages of the writing process in different contexts, what goals need to be applied, what they are expected to achieve, and how to achieve those goals. The knowledge acquired by the students in their use of technologies, and the testing of tools or resources, always allowed students to use the technologies but only when they were useful in the course of their writing process. What they learned from the exploitation of the writing process, in different contexts and situations, seems to have increased the awareness of the writing process that was reflected not only in texts produced in digital format but especially in analog format.

Conclusions and Implications

Some research data can assist teachers in designing writing activities in the classroom context with ICT resources. However, the success of interventions for the development of competencies and student performance will largely depend on the characteristics of the students and contexts in which they are inserted, as well as on the options of teachers in the strategies and learning methodologies.

It was also verified that on the one hand, allowing students to know explicitly the potentials of ICT resources throughout the writing process can have positive effects on their performance. On the other hand, the possibility of reflecting, experiencing, and deciding, with the help of the teacher, what resources are useful in the learning process not only increases students' knowledge about themselves and about the resources that surround them but also allows them to value their opinions and perceptions about the learning process.

It should also be noted that several authors in this area reinforce the pertinence of carrying out activities alternating between working in a large group, small group, and individually, allowing the construction of specific workspaces according to established objectives that respect the needs of the group and each student. They also allow a stimulus to collaboration, sharing, and creativity among mutually supportive students.

Also, the possibility of operating several theoretical recommendations for pedagogical practice

was evident together with the promotion of early detection and intervention of writing problems both individually and in groups. However, it also focuses intervention on the individual and the adjustability to the characteristics and needs of students.

The SRSD + ICT model, for example, with the integration of technologies in the classroom, also allows teachers to integrate the SRSD model associated with PBE and technologies, in preventive models in the classroom context, in order to promote and outline early identification, intervention, and assessment strategies to address the disadvantaged situations that students may present. When implementing this model, teachers should therefore consider the influence of perceptions and type of practices in the classroom in the teaching-learning process and listen more to students' options in their classrooms. Teachers should also encourage the profitability and integration of the technological resources of the families in the pedagogical practices of their classroom.

Finally, it is also considered fundamental to continuously and transversally promote the use of the processes of self-regulation in learning and to promote changes in writing practice in the classroom by approaching different forms and writing formats.

However, further studies need to be performed to reiterate or not the positive results obtained in this intervention, such as exploring different contexts (e.g., linguistic, cultural, educational level). Yet, these examples of integration of different elements and strategies to support the development of the writing of essays in the classroom context have allowed us to understand that it is possible to use technologies in the learning process of writing and understand the contexts and take advantage of the resources of the students' families.

Introduction

This entry presents the eXtreme Model-Driven Development approach as a low-code approach to collaborative application design and development that uses formal, executable models as the central asset for the prototype-based design and development. It introduces the concept and practice of low-code approaches in section “[Low-Code Application Development](#),” in particular its potential as a large-scale paradigm for future IT. It then introduces XMDD in sections “[XMDD: eXtreme Model-Driven Development](#)” and “[Experience in the Educational Context](#)”; it summarizes over a decade of teaching and learning experience at different levels, on different aspects of software design, and with different tools. It then discusses some aspects relevant to the educational and the adoption context (section “[Discussion](#)”). Section “[Conclusions](#)” concludes the entry with a summary and perspectives for the future.

Low-Code Application Development

Low-code application development environments are gaining attention in industry. Gartner reports as their Strategic Planning Assumptions that “by 2024, three-quarters of large enterprises will be using at least four low-code development tools for both IT application development and citizen development initiatives”, and “by 2024, low-code application development will be responsible for more than 65% of application development activity” (Vincent et al. [2019](#)).

Traditional application platforms provide runtime environments for application logic. They manage the life cycle of an application or application component, and ensure the availability, reliability, scalability, security, and monitoring of application logic.

A **low-code application platform (LCAP)** is an application platform that supports rapid application development, one-step deployment, execution, and management **using declarative, high-level programming abstractions, such as model-driven and metadata-based programming languages**. They support the development

of user interfaces, business logic and data services, and improve productivity at the expense of portability across vendors, as compared with conventional application platforms (Vincent et al. 2019).

Why Not in Education?

Low-code and no-code software design are not yet part of the standard curricula in schools or third-level education. The many reasons reflecting the beliefs of current educators can be summarized in three main theses:

1. Coding in **3G languages** is the state of the art in industry, thus it is what best trains students to be profession-ready today.
2. The **models** used in low-code environments may be more distant from “real code” (i.e., handwritten or hand-assembled code). Thus, they need substantial checks and post processing additional to the usual code-level quality assurance.
3. The more **formal models** adopted by some of these environments are mathematically underpinned, thus inherently difficult, and should be relegated to specialized training, like elective courses or a postgraduate level.

The cited assumptions in the recent Gartner study counters the first thesis: If a majority of enterprises is deemed ready to adopt this new trend in the next 5 years, these skills, methods, and tools are immediately relevant to educators in secondary school and third-level programs; their pipeline is in fact typically 3–5 years, and students should be prepared for the design culture and tool landscape, they will be asked to master upon graduation.

The model distance argument is a generational matter. Not long ago, 4GL like SQL and 3GL programming languages like C, C#, and Java were considered “too abstract” and “not controlling enough” by cohorts of programmers trained to believe that handmade byte or address level memory management is essential. Even within the 3GL cohort, the discussion about the “true need” and portability advantage versus inefficiency due to interpretation and inherent risk (thus the sandbox

concept) brought by the move towards virtual machines has pitted C++ supporters against Java adopters. Yet SQL and C/C++ are taught since 1980s, and Java became a prevailing standard in education in 1990s. The reason for their success and adoption in education and industry alike was a new kind of “simplification.” The essence of this simplification was a separation of concerns between a more declarative “what” (expressed in the SQL query, the Java program) and the more technical and detailed “how” connected with its execution. In the case of SQL, it was the database storage level organization, or the query computation. In the case of Java, it was the platform-specific virtual machine, mapping the bytecode to the specific instruction set and memory management practice of the target computational platform.

Significantly, the next educational waves have seen a split between a fail-fast approach geared to rapid prototyping, and model-driven but descriptive approaches à la UML (Unified Modelling Language) (UML 2.5.1 specification 2017) that focus on a better design prior to coding.

The rapid prototyping wing led to the popularity of script-like, interpreted textual languages like Perl, Python, Ruby, and Javascript. The traditional model-driven community developed tools with a graphical syntax, aimed at a spatial, visual, and standardized representation of entities, their many relations, but with no or limited execution capabilities.

As a consequence, standard curricula today predominantly adopt one of the 3GL languages as the learning basis for programming and its practice, provide instruction in one or more additional languages to address other paradigms (e.g., imperative, object-oriented, logic, functional), add some subset of UML to deal mostly with the static architecture (class diagrams, usually compared to ER diagrams) and some aspects of behaviors (sequence charts, state charts), topped by some other language for specific domains, like SQL for databases or XML-like languages for user interface design. These are seen as Domain-Specific languages, distinct from the core programming languages and thus heterogeneous, and in need of manual “bridging” or integration. One of the classic examples is the

Object-relational mapping (ORM) needed to translate between the classes of an object-oriented language and the relational entities in a database schema. Formal models are usually relegated to the theory modules, e.g., various kinds of automata, and data structures like trees and graphs, usually used in the classes that involve algorithms. Low code and no code are not foreseen.

Low Code as the Paradigm for Future IT

The reality of the Digital Transformation in the global society is such that not just the professional programmers need to master application development, but increasingly large segments of professionals in every domain of industry and society. There is an increasing pressure of Industry 4.0 and its pervasive digitalization in manufacturing and engineering, the increasing footprint of healthcare integration and digitalization, the connected health, smart aging, smart agriculture, smart cities, as well as the citizen developer initiatives sprouting locally, nationally, and globally. The software needed to deliver all this will have to be designed, co-developed, and evolved largely by individuals that are professionals in some domain area, but not trained to program in today's prevailing notion of programming.

The future IT will be more softwarized, as it happened with Software Defined Networks in the telecommunication industry and is currently happening with the Digital Twin in manufacturing.

Therefore, the future society needs an affordable yet precise and technically advanced solution to mass production of bespoke applications by professionals knowledgeable in their subject matter, who know “what” they need. They need affordable technical means to express with sufficient precision how these applications should work. Classical textual requirement engineering is not a good option: text fragments have too much distance from the running system. The prototype culture and the co-development approach promoted by XP, the eXtreme Programming movement (Beck and Andres 2004) were successful in fostering the collaborative approach between programmers and “customers,” but the hurdle of the cryptic code as the primary means of application creation still excluded the non-coders, the vast majority is of professionals. The situation depicted in Fig. 1 (left), where experts have to guess based on a large number of textual artifacts (right) that are handed over from one kind of expert to the next.

Figure 1 is taken from a project that followed the Rational Unified Process (Kruchten 2004): in RUP, many heterogeneous textual process descriptions, use case diagrams, and other UML diagrams are all aggregated in one single architectural model that is expected to embody all their imposed constraints on the eventual solution. This is hard to achieve and impossible to check, both at the design stage and on the implementation, which is a distinct collection of hand-programmed artifacts.

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding, Fig. 1 Mainstream approach

(left) with different types and collections of documents (right) – based on the Rational Unified Process (RUP)

Low code based on **executable models** is the combined paradigm that can deliver a design and development approach that is intelligible to the professionals, prototype based, and designed to master evolution and change.

The key elements of this low-code paradigm are the use of **models** instead of code, and the use of models that are **formal, integrated, and executable**. This is the XMDD approach.

XMDD: eXtreme Model-Driven Development

XMDD (eXtreme Model-Driven Design) (Margaria and Steffen 2008, 2009a) joins the best aspects of several successful trends (service orientation, aspect orientation, model-driven development, agility, eXtreme programming, generative programming, and full code generation) in modern software engineering for a *Continuous Model-Driven Engineering* (Margaria and Steffen 2009b) approach to the design of complex software systems. Its central artifacts are **models** that are **executable** and **formal**, i.e., mathematically underpinned.

Participation: Experts that Co-design

As a method, *Continuous Model-Driven Engineering* focusses on **consistent dialogue** of all involved stakeholders. This has two aspects: the systematic dialogue and its systematic consistency. The dialogue is possible due to the specific choice of models that are understandable by the application domain experts, the technical experts, and the programmers responsible for the implementation.

As sketched in Fig. 2, the entire development process is a cooperative, hierarchical, and interactive decision process where all the experts, including the programmers, collaboratively build and refine **one comprehensive model**. With the XMDD approach, the prototype arises directly from the executable models, which are implemented in a service-oriented way using service-oriented technology, or similar abstraction mechanisms for APIs and libraries. Because the models are formal, in this case specifically Kripke

Transition Systems (KTS) (Müller-Olm et al. 1999), the models can be analyzed with algorithms, for example, with model checkers (Clarke et al. 1999) and even constructed by algorithms, as in process synthesis approaches (Steffen et al. 1993; Margaria and Steffen 1998; van der Aalst et al. 2004).

This formality is essential to ensure consistency: The algorithmic analysis on the models reveals inconsistencies in a timely fashion and exposes misunderstandings well before the system component or the entire system are fully coded and tested. With the progress of the design and the decisions, the method leads to a natural incremental formalization (Steffen et al. 1996a). This formalization is in terms of models and properties: it helps collect, share, and evaluate the discovered change needs and their amendments as soon as they arise and to materialize them in reusable services, features, and properties.

Benefit: Coherence and Consistency by Design

As a low-code technology, XMDD enables each stakeholder – including application domain experts that cannot program – to continuously express requirements or decisions in terms of constraints on the models. Each development step or evolution step is a transformation of the models or a reification of the constraint set, which typically comprises many aspects and touches on several forms of knowledge.

Like in **model-driven design**, XMDD uses models. They are, however, also *formal*, thus mathematically analyzable, *loose* (Naujokat et al. 2012) to enable refinement; *executable*, to enable immediate prototyping and execution; and *semantic*, to enable reasoning within a specific knowledge or application domain.

Like in **service-oriented computing**, XMDD makes use of collections of pre-programmed and potentially externally hosted functionalities. APIs, instruction sets, web services, and traditional code libraries have been transformed into *native Domain Specific Libraries*, with representations at the model level. As shown, for example, in Jörges et al. (2007), Margaria and Schieweck (2019) in robotics, in Niese et al. (2001) in telecommunications, in Lamprecht et al. (2008),

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding,

Fig. 2 Continuous model-driven engineering in practice: the one thing approach with XMDD

Margaria et al. (2006) in bioinformatics, and in Airò Farulla et al. (2016) in security, they can be included as artifacts in the models, which are built bottom-up from GUI DSLs, collections of generic services, and these domain-specific collections.

Like in **eXtreme Programming**, XMDD welcomes essentially the participation by all stakeholders. Other than in XP, because XMDD is consistently low-code, nonprogrammers are able to work themselves with the models and the constraints, on par with the programmers.

Like in **Aspect-oriented approaches**, entire aspects are considered and dealt with separately from the design of the functionality. However, XMDD is not restricted to weaving as an aspect design and injection mechanism. For example, in DIME (Bosselmann et al. 2016), one of the recent XMDD implementations, roles, rights, and access policies are devoted an own model type and the weaving happens by compilation. Concerning security (Gossen et al. 2017, 2019) show that the insertion points where to inject the security-implementing code are kept implicit, basically every read and write needs to be adequately protected and the security-injecting compiler there described “knows” where and what to inject. The security aspect code is low-code itself.

Like in **Business Process Modeling**, another member of the low-code family, the main models in XMDD are processes. Called workflows in

scientific computing (entry ▶ “**Modeling of Scientific Workflows**” by Margaria and Lamprecht, this volume; Lamprecht et al. 2016a) or Service Logic Graphs in the telecommunication domain (Steffen et al. 1996b), the choice of the business logic as the main view central to the comprehension of the “story” behind an application or inside a hierarchical model is central to XMDD. Other than the popular datable models, Petri nets, or state charts, this approach adopt essentially activity diagram like models. The reason is that in order to understand what happens in one of those *insider*-oriented models, the user needs to master complex concepts like parallelism and the internal details of a system, essential for the notion of state, while this approach addresses stakeholders that are mostly *outsiders*, as in a truly service-oriented approach.

Continuous Evolution and Change Management

Knowledge, regulations, and various properties and constraints are adequately expressed in the following terms:

- **Properties** express the application’s intentions, internal policies, legal constraints, or technical frame conditions; they are typically formulated in logic, e.g., temporal logic for the workflow behaviors.

- **Loose process models** specify the rough distributed workflow from the management perspective, without concern for technicalities like type correctness, location, or interoperability that are taken care of elsewhere at a more technical level.
- **Symbolic type** information of services, processes, and data, sufficient to imply executability and enforced later by checking and synthesis technology
- Definitions of **roles and rights, timing and localization constraints, security, and exception handling**, which are integrated during aspect-oriented code generation.

The outcome is a methodology and toolset that delivers a simple and rigorous approach to managing changes, therefore continuous evolution and adaptation. It also delivers the integrated information and communication, and collaboration of heterogeneous roles and experts in a product management lifecycle as required by the increasingly popular DevOps integration. This happens through.

1. **Application-level control**, i.e., the continuous involvement of the customer and application expert along the entire systems' life cycle, including software maintenance and evolution
2. Continuous and ongoing **quality assurance** with different means at different levels and phases (requirement validation, simulation, model checking, data flow analysis, testing, and monitoring)
3. Specific support when **integrating** new technologies, services, or APIs, in a service-oriented way.

This way, XMDD significantly shortens the systems development lifecycle and it enables continuous delivery with high software quality.

Experience in the Educational Context

In practice, XMDD has revealed its power in the context of over 10 years of practice-based education and training. It was adopted in project-based courses, short trainings like Summer camps for

pupils or Summer schools for PhD students, to introduce formal methods-based concepts to software engineers, and to first-year students as a computational thinking scaffold to traditional programming.

The Models

The Service Logic Graphs (SLGs) are a behavioral counterpart to the SCA (Service Composition Architecture (Curbera 2007; OASIS: Service Component Architecture Website 2019) composites, and they are architecturally compliant with the standard for Service Composition (Jung et al. 2008). As shown in Fig. 3, jABC users develop services and applications by graphically composing and configuring reusable building blocks into (flow-) graph structures. The reusable building blocks are the basic functionalities of a service-oriented DSL.

These basic building blocks were called SIBs (Service Independent Building Block) in jABC, in analogy to the original naming of elementary telecommunication services (see (Margaria et al. 2005a; Magedanz et al. 2007)). SIBs have one or more outgoing edges (branches), which depend on the different outcomes of the execution of their functionality. The resulting models, that orchestrate SIBs, are called Service Logic Graphs (SLGs). The terminology used in the SIB libraries and in the SLGs is tailored towards the considered target user group, typically the experts of the current application domain, without requiring any IT knowledge. Thus, they are adequate to represent the behavior of a service to business developers, customers, end users, and any beginners in the realm of IT.

The Tools and Platforms

As shown in Fig. 4, over the last 15 years were developed: primarily three XMDD platforms: jABC, Cinco, and DIME.

The jABC tool was developed in Java since 2003 and applied in numerous industrial and scientific projects (Bajohr and Margaria 2005; Hörmann et al. 2008; Margaria and Karusseit 2002; Neubauer et al. 2013). Driving forces for the further development were the scientific workflow projects reported in more detail in the entry ► “Modeling of Scientific Workflows” by

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding, Fig. 3 Model and its execution in jABC 3. (From Kubczak et al. (2006))

Margaria and Lamprecht, this volume). In parallel, the framework formed the backbone for numerous extensions, like the Electronic Tool Integration platform ETI (Steffen et al. 1997) and its variant jETI (Margaria et al. 2005b), the Genesys (Jörges 2013; Jörges et al. 2008), and PROPHETS (Process Realization and Optimization Platform using Human-readable Expressions of Temporal-logic Synthesis) (Lamprecht et al. 2010) plugins for code generation and model synthesis, and finally the DyWa tool for developing dynamic Web applications (Neubauer et al. 2014). Currently, the jABC heritage of designing domain-specific modelling tools is taken over by the Cinco Meta-tooling suite (Naujokat et al. 2018), which lifts domain modelling to the meta level.

jABC3

In particular, jABC3 provided since 2006 a very stable platform to work with application-level tracing and simulation models that are conveniently executable. Figure 1 gives an impression

of jABC3 in action, using an example workflow from a project on LC-MS data preprocessing and analysis (Kubczak et al. 2006). The SLG on the canvas has been created using SIBs from the service library (displayed in the upper left of the window) in a drag and drop fashion, and connecting them with labelled branches representing the flow of control. As soon as the parameters of the SIBs have been configured (in the SIB inspector at the lower left), the workflow is ready for execution. The small window in the upper right corner of the figure is the control panel of the Tracer plugin. In the picture, the Tracer window indicates that it is currently executing a SIB, and the green-colored branches of the model on the canvas visualize the current execution point and the path it followed.

The jABC3 release provided the core framework and the corresponding editor as graphical user interface, as shown in Fig. 1, but also a wealth of further features and capabilities for supporting workflow development that became available over the years:

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding, Fig. 4 Chronology of the

XMDD family of tools from jABC to Cinco. (Adapted from Lamprecht et al. (2016a))

- The **GEAR model checking** plugin (Bakera et al. 2009) for model-wide verification of properties
- The **Genesys code generation** plugin (Jörges 2013; Jörges et al. 2008).
- The **IconEditor** for easy manipulation of SIB icons within the jABC GUI
- The **Layouter** plugin, which supports the automatic layout of larger SLGs,
- The **LocalChecker** plugin that can check defined properties of individual SIBs
- The **SIBCreator** plugin that can be used by work-flow designers to create code skeletons for new SIBs which are implemented later
- The **TaxonomyEditor** plugin, with which a collection of SIBs can be renamed and (re) arranged in a hierarchy of categories in order to optimally fit the domain structure
- The **Tracer** plugin as the inbuilt interpreter for SLGs that allows for their immediate execution

and two demo projects (a simplified web shop and a Turtle Graphics process project) designed to provide easy-to-follow examples and starting points for novice users.

jABC3 was successfully used in a number of industrial projects spanning telecommunication services, supply chain management, bio- and geo-informatics, logistics, automation, robotics, and health care. In all these cases, agility at the

customer, user, and application level was the key feature for success.

The projects often also made use of the associated jETI (Electronic Tool Integration) platform (Margaria et al. 2005b) to ease the integration of third-party tools as services for use within the jABC workflow framework. Initially predominantly adopted in the field of bioinformatics, where a domain-specific incarnation of the framework called Bio-jETI was established, applications of jABC soon emerged also in further scientific domains, such as geoinformatics and medical research (see, e.g., Al-areqi et al. (2014) and Lamprecht (2014)).

Cinco: Generating Tailored Frameworks

Cinco is a framework for the model-driven development of graphical modelling tools. It can be used for the automatic generation of a wide range of graphical modelling tools, as shown in Naujokat et al. (2014) for modelling concurrent systems.

On the one hand, it is used to develop XMDD modelling environments (like DIME (Bosselmann et al. 2016), WebStory (Lybecait et al. 2018), or AdventureGame (Gossen et al. 2018)), which all are regularly used in teaching.

On the other hand, it follows itself the XMDD approach. This means that the graphical modeling tools developed with Cinco, like DIME and the ones mentioned above, are actually not hand-

programmed but instead modelled in an abstract high-level specification and then code-generated into fully functional modelling environments, in a pure low-code approach.

The Cinco SCCE Meta Tooling Suite (<http://cinco.scce.info>) provides a generator-driven development environment for domain-specific graphical modelling tools that form the next generation of XMDD frameworks. The point of Cinco and the generated Cinco-products is to support a much broader use context envisaged for the design and modelling tools: Service-Centered Continuous Engineering (<http://scce.info>). SCCE extends the continuous design and continuous deployment of (Ståhl and Bosch 2014) to a continuous lifecycle support paradigm where users co-define and comanage the design and the evolution of deployed systems. This approach requires the coherent support of different levels of expertise and different concerns among the cooperating participants, and thus requires adaptability also of the technological means, including the design environment (like the jABC) itself.

In fact, one can observe that the more a software framework is tailored to a specific domain or even application, the easier is its uptake especially by non-CS user communities. Thus, Cinco's capability to generate the entire low-code design, development, and, in future also, deployment will open these technologies to a much broader audience. The approach is to tailor also the development tools to the application domain and the expertise of the users. Cinco goes further than the provision of suitable domain-specific service libraries by directly hooking onto domain-specific practices, conventions, and individual preferences for workflow or process modelling.

In the reported experience, using XMDD tools is generally well understood by students (graduates as well as undergraduates). Thus, developing business/application logic using a pre-defined library of service-oriented components (SIBs) proves to be quite intuitive. The same applies on the meta level when using Cinco-level services (such as meta plug-ins for "code generation" or "validation") for the development of their domain-specific modeling tools.

Developing XMDD tools seems instead more difficult. Here, students regularly struggle with the inclusion of SIB-like concepts into their DSLs. While not much can be done to lower the inherent complexity of the (meta-level) concepts, as many technical hurdles as possible are being successively removed from the Cinco framework. Cinco already has a concept for building tools with component libraries via an inter-model linking feature called "prime references," and in the future this feature will be extended by supporting efficient browsing/searching for components in such libraries, and simplifying the development of components with parameters, as was done for the inputs/outputs of SIBs in jABC and DIME.

DIME

DIME can be regarded as the Cinco-generated version of jABC; however, it is already tailored for the generation of tools that run in a browser. The experiences from three project group and five MSc theses in TU Dortmund matches very closely that with the jABC.

The Courses

Learning Modelling

Student projects/coursework in the Masters in Bioinformatics and Geo-visualization(86): Since 2008, the meanwhile mature jABC3 had also been an education tool. It was used to teach a variety of university courses on process modelling and service-based software development in the field of scientific work-flows to Bachelor and Master students of Computer Science and related disciplines, such as Business Informatics, Geo-visualization, and Bioinformatics. Although the students came with extremely different levels of prior knowledge in programming and software engineering – ranging from complete novices to experienced developers – they could even-handedly participate in the interdisciplinary oriented courses. By the end of 2015, more than 200 students had attended the courses, and accordingly the approach has been validated in both research and education environments. Detailed experience reports about the courses are

available in entry ► “[Modeling of Scientific Workflows](#)” by Margaria and Lamprecht, this volume, Lamprecht et al. (2016a), and Lamprecht (2014) for natural science, and in Gossen et al. (2018), Lamprecht et al. (2015), and Bordihn et al. (2015) for software engineering and introductory programs to Computer Science and programming. It is also used in connection with games as a low-threshold approach to teach Computational Thinking and the logic of programming constructs to various kinds of beginners as reported in entry ► “[Modeling of Games and Game Strategies](#)” by Margaria and Lamprecht, this volume as well as in Gossen et al. (2018), Lamprecht et al. (2016b), and McInerney et al. (2017).

As soon as the modules on Introduction to Computer Science at the University of Potsdam moved to a significant Problem-Based Learning component, for a number of years the student projects comprised lectures and laboratories on XMDD-based process modelling, followed by individual projects carried out with jABC3. Already in 2015, this collection comprised 86 scientific workflow projects, 34 of which were bioinformatics applications, 37 were from the geoinformatics domain, and 15 realized other kinds of scientific analysis processes. The students could not program. Instead, they used prepared native DSLs of the application domain. The projects were not predefined by the lecturers but proposed by the students themselves. Having already graduated in a natural science discipline or being advanced undergraduates, they were able to identify and tackle a reasonable data analysis problem from their respective domain. Thus, even if the scope of these projects was limited due to the time and resources available, they provide representative examples of scientific workflows created in a low-code development environment by application domain experts who cannot program in the traditional sense.

Learning (Regression) Testing and Model Learning In **testing** and in particular regression testing, given a product and a new candidate release, validate that the new release still supports the vital features of its predecessor. This model-

based approach allows here to go beyond the classical approach, where the test executions of the two releases are required to match precisely. Overcoming this original restriction helped to drastically reduce the number of irrelevant test failures.

In **model learning**, given an executable system together with an interface for remote execution, corresponding behavioral model are automatically inferred via testing. This feature is invaluable whenever one attempts to integrate third party/legacy components, or to discover a posteriori the effects of some customization on known systems.

Specifically addressing testing and testing-based model recovery, since 5 years automata learning (Isberner and Howar 2014; Steffen et al. 2011) based on low-code applications of XMDD has been used in the project-oriented course Web Technologies II at TU Dortmund. Automata learning has been taught as a means to establish a bridge between classical Web development and model-based thinking.

In the first years, only 20–30% of the 80–60 students taking the course every year were able to integrate this technology (cf. (Isberner et al. 2015)) into their projects. After easing the learning framework by providing a simplified Web interface (Bainczyk et al. 2016, 2017), this percentage went up to 80–90% in recent years. In the meantime, students start to appreciate the learning technology as a powerful support for testing-based quality assurance.

Learning Application and System Design in Capstone projects

TU Dortmund has a mandatory Project Group (PG) for master students similar to capstone projects elsewhere, but training the students through larger-scale collaborative projects: in a PG, 12 students work on a single complex project for a whole year.

In recent years, many PGs used Cinco to develop specialized XMDD languages for a variety of domains. Students are taught a deep understanding of XMDD principles: they *use* an XMDD-based framework (mostly Cinco) and also experience the (guided) *development of an*

own domain-specific XMDD framework for the domain in question.

Recently covered topics span a broad variety of application domains:

[2019] The **Alexa PG** created a modeling environment used to develop “skills” for Amazon’s Alexa Voice Service. Central to this environment is a Cinco-based graphical modeling language for the specification of User/Alexa interactions in a flow graph style. Those “Alexa Skill Workflows” are then fully generated into code and deployed into Amazon’s cloud services.

The PG realized additionally integration with the DIME framework, so that the business logic underlying the skills can be modeled using DIME processes and data models.

[2018] The **ACC++ PG** developed a collection of domain-specific languages for the domain of specifying and testing autonomous driving functionality. The project had two aspects: the definition and implementation of DSLs for the specification of Advanced Driver Assistance Systems (ADAS) based on sensor inputs and actor outputs, which resulted in a specialized Statechart language. It also developed DSLs for test scenario specifications that supported the automatic simulation of the ADAS systems.

[2017] The **GenGa PG** developed an engine for “Generative Game Development” on top of the DIME framework. Focusing on board games and simple animations, the project resulted in various Cinco-based graphical languages for the specification of game boards, tokens, players, and logic.

[2016] The **Bridging the Gap PG** developed a whole family of graphical DSLs for the specification of control software running on an industrial plant. (Wortmann et al. 2016) The variety of DSL developed in the project and their connection and role is illustrated in Fig. 5.

Before Cinco, the jABC framework was used at TU Dortmund as primary technology for XMDD teaching in PGs. Also there it was used to teach XMDD concepts on both the meta level

and the application domain level, but with far less clarity and framework-based correctness checks and automation. The jABC was used in PGs concerning

- KrisenPlan: Planning Games for crisis management in Data and Computing centers (PG592, 2015)
- ProBio: Process-oriented management and analysis of biomedical data (PG586, 2014)
- AgES: Aspect-driven development of secure control systems (PG576, 2013)
- SASSD: Situation-Aware Semantic Service Discovery (PG566, 2012)
- Eclipse4Bio: Use of jABC to extend Eclipse to a domain-specific design and development system for biology-related workflows (PG558, 2011–2012)

In addition to the use of XMDD and Cinco in the undergraduate and graduate level education, several intensive short courses (typically 2 days) at the PhD or graduate school level were held in various countries and locations.

In the International School on Tool-based Rigorous Engineering of Software Systems (STRESS), there were specific trainings on.

- Bootstrapping in the Cinco framework: uses of a graphical metamodeling language developed with Cinco for Cinco (2018)
- Language-Driven Engineering applied on the domain of decision diagrams for email classification (2018)
- Using the “WebStory” modeling language to specify interactive browser games and extending the environment with Cinco metamodeling and code generation (2016)
- Building a PetriNet modeling and simulation environment for simple place/transition nets with Cinco (2014)

Learning the Connection Between Agile Modelling and Design Thinking

In 2017, a week-long course on Agile Design Thinking: Agility through Extreme Model-Driven Engineering took place at the Politecnico di Torino (Italy) as part of the interdisciplinary

Overview Diagram

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding, Fig. 5 Overview of the four

diagram types (generated with Cinco) in the case study of (Wortmann et al. 2016)

Didattica di Eccellenza in the SCUDO graduate school. The course included theoretical and practical units, and a subsequent individual project with DIME by the students. The course showed how to achieve (a) application-level control, i.e., the continuous involvement of the customer and application expert along the entire systems' life cycle, including software maintenance and evolution, together with (b) continuous and ongoing quality assurance with different means at different levels and phases (requirement validation, simulation, model checking, data flow analysis, testing, and monitoring), and (c) specific support to integrate in an easy and noninvasive fashion new technologies, in a service-oriented way. The key to the approach is to view the whole development process as a creative endeavor that needs to explore, evaluate, optimize, and evolve both the “thing” under design and its context and human/social aspects. In this sense, it is an agile embodiment of the “Design Thinking” paradigm.

In 2018, a shortened course took place in Limerick (2 days).

Learning Software and Systems Verification

Given a model and the rules of the game, like business rules, policies, governance, or compliance requirements, check whether the model respects the rules. If not, provide detailed diagnostic information – typically in terms of a violating run.

In the Foundations of Semantics and Model Checking in a Software Engineering Course (Bordihn et al. 2015) introduced in 2010 at the University of Potsdam in Germany, described how they included a selection of formal methods in a foundational Bachelor-level Software Engineering course. They showed how to introduce the basic elements of modeling and programming language semantics, and discuss how to address the theory and practice of model checking within the scope of the two semesters of the course. In

particular, the first term, SE1(6ECTS) focused on design: the domain level and modeling languages, addressing and contrasting traditional versus agile software development. It introduced model-driven (MDS) approaches, domain-specific languages (DSLs) as fundamental feature of MDS approaches, and meta-modeling as a tool for determining the abstract syntax of a DSL. While the focus was on the concepts and the modeling attitudes underlying these approaches and technologies, some of them were practiced using corresponding analysis and modeling tools.

- **SLGs as Formal Models:** Kripke Structures, Labeled Transition Systems, and Kripke Transition Systems are introduced as suitable abstract model structures. Semantically, SLGs are in fact Kripke Transition Systems (cf. (Müller-Olm et al. 1999)) that combine classical Kripke Structures (cf., e.g., (Clarke et al. 1999, Chapter 2)) with Labeled Transition Systems (cf., e.g., (Kruchten 2004)) into model structures where both states and transitions are labeled. As such, they are directly amenable to formal analysis techniques, in particular to model checking.

The processes are modeled as SLGs using only Prototype SIBs, like the abstract web shop process shown in Fig. 6. These SIBs are pure modeling means, as they do not have an actual implementation, but as the implementation is not relevant with regard to this kind of abstract model checking, they are sufficient for the purpose. Then system requirements are formulated as temporal properties.

- **Temporal Logic Properties as Constraints:** Starting from the propositional logic already familiar to the students, Hennessy Milner Logic (HML) (Beck and Andres 2004),

Propositional Linear Time Logic (PLTL, cf. (Margarita and Steffen 2009b)) and Computation Tree Logic (CTL, (UML 2.5.1 specification 2017, Chapter 3)) are introduced as tailored domain-specific languages to formulate behavioral properties. While GEAR is internally a mu-calculus model checker, only CTL would be strictly necessary. HML and PLTL are included primarily for didactic reasons, as they provide good scaffolding for understanding CTL, especially regarding the role of the temporal operators along the paths and the path quantifiers. In the two associated labs, students practice the use of HML, PLTL, and CTL by modeling intuitive properties in terms of these logic languages thereby learning to interpret logical formulas in a comprehensible way.

- **Model Checking:** Finally, the students learn how SLGs can be viewed as Kripke Transition Systems, how to use GEAR to assign atomic propositions to the SIBs of the SLGs, how to enter logical formulas, and how to check and debug systems with GEAR. The use of GEAR is demonstrated by means of some simple examples, where the level of the student's independence is gradually increased.

With the GEAR formula manager, students can edit CTL formulas and document them with natural-language descriptions. The model checking inspector displays all currently available properties, and one can toggle between the formulas (Fig. 7 top right) and their high-level descriptions (Fig. 7 bottom left). In the hands-on sessions, students learn to find out which properties hold for the entire model (i.e., for the start SIB) or individually for each node in the model. The nodes where the formula holds/does not hold are highlighted by

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding, Fig. 6 The abstract web shop process (standard and Atomic Propositions view)

eXtreme Model-Driven Development (XMDD) Technologies as a Hands-On Approach to Software Development Without Coding, Fig. 7 Checking a single property for the whole model

green/red boxes, respectively, as shown in Fig. 7 (right).

The students work in their projects with larger and more complex examples than the illustrative tiny model shown here.

The course was attended by over 250 students. Approximately half of the participants were enrolled in the B.Sc. Computer Science (2010–2014) or B.Sc. Computational Science (2015); the other half of the participants were students in the B.Sc. Business Informatics. There has been no observable difference between these groups regarding the achievements in the exercises, exams and projects. There was, however, a significant difference among the skills developed by these students and those of the precedent years: While the previous generations were more confident in architectural issues and coding skills, these students have a more intuitive confidence with application development and with mastering a number of different technologies. The advantage of this abstract and behavior-driven modelling manifested itself in their approach to the subsequent module on Foundations of Service Engineering, where the black-box character of components is really central. The familiarity with the basic formal methods concepts was also advantageous in the subsequent specialized course on Formal Methods in System Design

(FMSD): taught in an e-learning fashion via teleconference-based lectures shared with the TU Dortmund and complemented by local tutorials and laboratories. It was clear that the Potsdam students had a smoother approach to the more technical material in FMSD due to their previous experience with the basic concepts.

Learning Meta-Modeling and Language Engineering

Every term, an average of 20 Bachelor students in Computer Science – mostly in their final year – are taught in TU Dortmund the XMDD paradigm as well as the fundamental concepts of meta-modeling and language engineering using Cinco. This concerns both textual and graphical modeling languages.

The course itself is split in two parts: some weeks of classroom teaching along with tutorial-style assignments are followed by a practical assignment to be solved autonomously in pairs. The practical assignment includes the development of graphical editors with Cinco in order to realize a configurator for a specific product using well-defined components that are defined in a textual language. Here the focus is on creating and linking a heterogeneous landscape of languages in order to build and maintain a central development artifact in a consistent manner, following the “One-Thing-Approach” (Margaria and

Steffen 2009a). The assurances of syntactic correctness as well as the validation of the model semantics supported by the “consistent by construction” approach in Cinco are vital aspects to achieve this goal.

The course and the development of Cinco mutually enrich and reinforce each other, in particular in terms of simplicity. They observed that both the quantity and quality of the solutions created by the students noticeably increased with Cinco as it became over the year a more intuitive development tool. However, it is remarkable that even students with little or no experience in meta-modeling and language-driven development can produce sophisticated solutions with Cinco after a short training period.

Discussion

XMDD replaces the global and slow roundtrip-based communication between stakeholders often working with completely different means. This contrasts with “traditional” programming-first approaches as well as with model-based but document-centric software engineering approaches like the Rational Unifying Process (RUP). It can be regarded as systemized, low-code, and tool-based enhancement of eXtreme Programming and agile methods (see <https://www.agilealliance.org/agile101/the-agile-manifesto/>) like Scrum (see [scrum.org](https://www.scrum.org)).

Like XP for programming in the small, the XMDD approach revolutionizes process and application development by replacing the typically long intervals between contract-and-requirements time and delivery-and-acceptance time – with all the associated pitfalls – by a continuous, cooperative development process that immediately reveals misconceptions so they can be addressed as soon as they arise.

Why Is it Relevant

Understanding of the application under construction – the user experience – builds naturally along the way. In particular, this new view of cooperation between the customer and the contractor/developer reduces the need for complex and expensive specification documents. These all too

often impose design decisions before the customer can judge their impact, and they often turn out to be obstacles when adjusting the project in the overall context. In contrast, the cooperative development and evolutionary style of XMDD supports the agile adjustment by focusing on the following points:

- **Continuously update the customer:** The impact of each design decision on the application logic becomes apparent via the OTA, which provides customers with a continuously updated user experience.
- **The Focus on the application logic** lets developers repair and modify at the level where the need appears, while following the service-oriented paradigm makes noninvasively exchanging or integrating third-party functionality easy.
- **Constraint analysis:** At any stage, developers can verify the formulated constraints via local checking and data-flow analysis to ensure parameterization and configuration constraints, and can use model checking to ensure global properties concerning protocols, version compatibility, policies, or legal process requirements.
- **Code generation:** Once all required elementary services are implemented, stand-alone code can be generated to fully match the tracer behavior and also manage aspects like role specifications, rights, permissions, security, load balancing, and long-running transactions management.
- **Monitoring:** The runtime environment tracks resource consumption and availability as well as the progress of individual process instances according to their defining models.

These points can be considered the cornerstone for new customer-oriented software development, which aims at raising quality and fit of produced solutions while lowering the total cost of ownership.

The Benefit to Education

From an educational point of view, there are three main benefits, as the XMDD-oriented, tool-

centered teaching approach allows students to experience the impact of

- Design thinking (think the project from the users' perspective)
- Computational thinking (put the user process in the center) and the
- Generative approach to system development (trust the tool chain!)

Today, facing service orientation and an increasing interest in user-defined business processes, lightweight formal methods should be integral part of the standard academic software engineering education. The experience in the foundational Bachelor-level Software Engineering course with four embedded formal methods components at the University of Potsdam in the period 2010–2015 and the first year bootstrap module in Limerick (2016–2019) have confirmed the usefulness of the computational thinking approach and the choice of using XMDD in a modern, low-code, generative system development framework.

Choosing only so-called lightweight formal methods, i.e., methods with fully automatic algorithms and tools (like type checkers and model checkers), and not theorem provers or proof techniques for program correctness like Hoare-style program verification (both presented at length in other courses), was done on purpose, in order to provide scalable approaches that have a low threshold to adoption, ease of reasonably confident use in the small, and a high ease of embedding in a full-fledged model-driven IDE.

While high-end Formal Methods continue to require a deep knowledge of the mathematical concepts and formalisms, IDE-embedded Formal Methods should be made available systematically to the next generation of Software Engineers as part of their basic profession-oriented education. Like basic English has successfully become within a generation a standard in schools, establishing itself culturally as the “lingua franca” of international communication, the ability to take a domain-specific perspective, to think in terms of domain-specific properties, to formulate them in

such a way that both a user and a tool are able to work with them, and the ability to conduct verifications on early models of a system are the key to a better understanding between IT professionals, in particular Software Engineers.

Another advantage is the ingrained sense of accountability and ownership that comes with the ability and habit of verifying early and verifying often, by means of tools that take an objective perspective (other than user inspections) and provide a third party repeatable outcome. With all the limitations and drawbacks known of the FM tools and approaches of today, such a step towards accountability for decisions and outcomes early in the design constitutes a central shift towards maturity of the professional figure, competence beyond the production of code, and ultimately towards establishing a new concept of ethics and responsibility in the Software Engineering profession.

Conclusions

When the XMDD-paradigm entered software engineering classes almost 20 years ago, this low-code and formal approach was not always appreciated. In fact, even today there is some resistance from the classical programming-oriented educational establishment. Some of the arguments are that the established Computer Science and Software Engineering curricula, e.g., by the ACM, do not talk at all about low-code approaches, include models in the traditional descriptive sense and not as executable artifacts, and list formal methods as advanced topics, to be retrofitted on the students as electives once the foundations have been laid through code-first approaches. One can counter that those curricula, as of today, do not list Artificial Intelligence or Machine Learning either: this is a consequence of the well-known fact that, like standards, such curricula trail, instead of leading, both the knowledge development and the adoption in practice.

Today's general movement towards the application expert and the increasing prominence of design thinking indicates, however, that XMDD is on the right track. In particular, with the

growing maturity of the XMDD tools, students start to appreciate the potential and the power not only in class but also in “real life.” This is reflected in the growing number of students explicitly asking for corresponding thesis topics. If Gartner is right in forecasting the massive adoption of low-code development environments, the next generation of ACM curricula will likely prominently include them.

Social media; Social networking site; Technology-enhanced learning; University classroom education

Introduction

Recent studies have shown that social media technology plays a role in facilitating teaching and learning in higher education (Bryant et al. 2014). Social media is recognized as a popular social communication channel, and in recent years, there is an increased interest of educators for using social media in higher education as a technology-enhanced learning environment. In addition, the rapid advancement of technology, such as social media, offers new opportunities to university students for more access to information and interaction, increasing their chances of achieving better academic performance and

affecting education in terms of pedagogical purposes (Laskin and Avena 2015).

The use of social media by university lecturers and students has been an interesting research area for educationists and social scientists. The Social Media Survey 2013 by Pearson shows the increase use of social media for teaching by educators and faculty professionals because they see the potential in applying and integrating social media technology to their teaching practices (Seaman and Tinti-Kane 2013). This creates a growing phenomenon for the educational use of social media to create, engage, and share existing or newly produced information between lecturers and students and among students (Lee et al. 2015). Some researchers perceive social media tool as an effective educational platform because it allows educators to make the classes more interactive; on the other hand, there are researchers who state that the use of social media has hindered the achievement of student learning outcomes (Lee et al. 2015).

Although social media is considered a double-edged sword, research on social media use, such as Facebook, in higher education has grown rapidly with an increasing number of educators and researchers who believe that Facebook provides an environment that supports university students' active learning. Facebook is the most popular social networking site which has received considerable attention from a large number of research areas particularly in social sciences (Manca and Ranieri 2016). Facebook was established in

February 2004 by Mark Zuckerberg for Harvard University students and later opened for public membership in 2006 (Grossman 2010). To date, Facebook has 2 billion monthly active users (Techcrunch.com 2017). Among them, university and college students hold the highest percentage of active Facebook users, extensively sharing information on Facebook (Abdulahi et al. 2014), and used it as a tool of relaxation and entertainment in between their studies during the university and college days (Kashif 2013).

For example, Facebook groups are used by students for creating discussion forum and receiving updates from their instructors on their newsfeed and by instructors for sharing and communicating with their students about course information, examinations, assignments, and announcements through the group posts (Al-Bahrani and Patel 2015). Despite the excitements surrounding the potential of Facebook in higher education, researchers have waved the yellow caution flag on the over-privileging the site for actual pedagogical purposes. Some researchers who are not positive about Facebook use reported that the negative feelings were a recognition that the use of Facebook for English language learning simply had not helped improve students' English language (Tess 2013).

Regardless of the pervasive use of Facebook in higher education, there is a mixed result on its perceived impact for teaching and learning in classroom education. With that in mind, this study, part of a work-in-progress research project, provides insight about the adoption of Facebook by lecturers and students in a formal classroom education in Malaysia, as well as how the lecturers and students perceive Facebook could enhance learning experiences, supporting and improving teaching practices. The preliminary findings of this study contribute to the understanding on how and why lecturers and students leverage Facebook as a teaching and learning tool in Malaysian higher education classroom. The remaining sections of this paper is organized as follows: a review of literature on the uses and impacts of Facebook in higher education, a methodology section which describes the procedure of data collection and analysis, a findings and

discussion section which present the answers for the two research questions, and lastly a conclusion section which summarizes the findings of this study in achieving the research objectives.

Literature Review

Research on Facebook use in Malaysian educational contexts has been growing at a rapid rate. The criteria have taken into consideration the inclusion of the studies in this literature review including the scope of study and the academic profile of the journals. Firstly, the selection of literature is based on the uses and impacts of Facebook in higher education. The keywords used for finding these studies are "Facebook and higher education," "Facebook and Malaysian higher education," "Facebook use in higher education," and "uses and impacts of Facebook in higher education." Next, the literature is based on empirical research published in scientific journals, postgraduate theses, dissertations, and other contributions such as conference proceedings and research reports. Lastly the literature is searched through EBSCOhost, Google Scholar, and the Google search engine. The following paragraphs discuss the two themes of the study: uses of Facebook in higher education and impacts of Facebook use in higher education.

Social media, such as Facebook, is an established part of the communication networks and has great potential for networked learning, both within and outside the boundaries of the physical classroom (Freeman 2014). Besides, Facebook has gained a unique position as a learning technology for educational purposes because students created a Facebook group for managing educational content and it provides a conducive environment for student interaction (Ahern et al. 2016). Literature reveals that it is proven to be feasible for learning English in Facebook due to its features which "are able to engage students in meaningful language-based activities" (Kabilan et al. 2010, p. 185). In addition, Manca and Ranieri (2016) in their analysis show that Facebook is still mostly considered as an alternative to traditional learning

management systems (LMS), though they concluded that the pedagogical affordances of Facebook are still partially implemented.

The use of Facebook by lecturers and students as reported in the literature is due to the “dynamic development of the Web 2.0 and new trends in the social media field” (Tanta et al. 2014, p. 86), and the usage could be explained through the Uses and Gratifications Theory as why and how individuals actively select specific media outlets to satisfy specific needs (Katz et al. 1974, as cited in Ifinedo 2016). Scholarly research has drawn upon the Uses and Gratifications Theory to examine the consumption behavior and motivations of individuals using Facebook – information exchange, conformity, freedom of expression, social maintenance and recreation, making new connections, socializing, entertainment, self-status seeking and information, passing time, showing affection, following fashion, sharing problems, demonstrating sociability, and improving social knowledge (Phua et al. 2017).

In the Malaysia context, most researchers agree that the implementation of Facebook in Malaysian higher education produces positive impacts, especially in language and writing classes (Ng and Maniam 2015) and improving students’ academic performance (Helou and Ab. Rahim 2011). Ng and Maniam (2015) investigated the perceptions and attitudes of 15 students from a college in Peninsular Malaysia toward the use of Facebook group discussions. The results show a positive attitude of the college students on the use of Facebook group discussions, and there is a “significant effect of Facebook group discussion on students’ writing performances” (Ng and Maniam 2015, p. 36). In another research, Helou and Ab. Rahim (2011) measured students’ perceptions on the use of social networking sites and its impact on students’ academic performance. Based on a survey with 30 undergraduate and postgraduate students of a public university in Southern Peninsular Malaysia, most respondents felt that social networking sites have more positive impact on their academic performance due to its use “for various academic activities such as communicating with the faculty and university authority, communicating with lecturers and

supervisors, making academic discussions with classmates and chatting with friends in respect to topics of educational interest. While the negative impacts of the social networking sites towards their academic performance are considerably low” (Helou and Ab. Rahim 2011, p. 7).

Lastly, Facebook also brings benefits in students’ learning experience as a platform for online discussion (Abdul Rahman and Mohd Amin 2014), a supplementary tool for team-based learning (Rasiah 2014) and an alternative tool for student engagement (Sim et al. 2014; Haque et al. 2015). Abdul Rahman and Mohd Amin (2014) examined the effectiveness of Facebook as a teaching aid for a subject at a private university in Malaysia. Through a descriptive questionnaire survey with 300 students, the results demonstrate that “the relationship between the students and their lecturers can be improved and this indirectly will influence the students’ performance in the subject” (Abdul Rahman and Mohd Amin 2014, p. 333). Rasiah (2014) on the other hand conducted a content analysis on 122 students’ reflection journals on their learning experiences of undertaking the group and individual projects as well as their perceptions on the effectiveness of Facebook use in enhancing their learning experience and competences. The author concludes that students perceived the use of Facebook as beneficial for instructional purposes and there is clear evidence on the effective use of Facebook in enhancing team-based learning outside the classroom, complementing face-to-face lessons (Rasiah 2014).

In terms of student engagement, Sim et al. (2014) collected the data through a student survey, postings in the Facebook group, and a short essay from the lecturers concerning their experience of using Facebook as a tool to engage students in the class. Results show that the feedbacks received from both lecturers and students were positive because Facebook features encouraged student participation and engagement in Facebook groups, and the authors conclude that Facebook is the suitable tool for student engagement (Sim et al. 2014). Haque et al. (2015) distributed a structured survey to 500 students of various private and public higher learning institutions in Malaysia.

Data drawn from 398 usable questionnaires shows that students perceived Facebook as an alternative learning tool in the Malaysian higher learning institutions and “the characteristics of social networking sites such as ease of use, intricacy, adaptability and observability might affect the attitudes towards adoption of Facebook as a learning tool” (Haque et al. 2015, p. 1631).

Prior research shows that Facebook is useful for learning environments (Kabilan et al. 2010) and Malaysian students have been using it for informal learning purposes (Hamat et al. 2012); this in return has resulted a positive impact on their academic performances (Al-Rahmi and Othman 2013). Facebook is perceived as an innovative and effective tool in a student-centered learning environment because it “created a more positive and less-threatening learning environment which enhanced the students’ engagement and learning experience while creating a stronger rapport between each other and with the lecturer” (Rasiah 2014, p. 377). In addition, lecturers of Malaysian universities also begin to use Facebook to complement their current teaching and learning practices (Hamid et al. 2011).

Although positive results of Facebook use in higher education were shown in prior literature, differences were found “between the well-proven potential of technology-enabled learning and the less consistent realities of technology use within university teaching and learning” (Henderson et al. 2015, p. 1). Lim et al. (2014) further claimed that successful adoption of Facebook in Malaysian higher education institutions depends on many factors because students, academics, and the institutions themselves have views and practices that do not necessarily align. The use of social media technologies, especially Facebook in higher education, is not an easy and straightforward process. Therefore, more research efforts are needed to integrate social technologies in higher education and for effective use in formal learning contexts (Deng and Tavares 2015).

A mixed result in the empirical literature shows inconclusive evidence on the uses and impacts of Facebook in higher education classroom. Drawing on the literature review of Facebook use in the Malaysia context, two research

questions guiding this study are: (RQ1) How is Facebook utilized in Malaysian higher education classroom? (RQ2) How is Facebook perceived as an effective teaching and learning tool in classroom education?

Methodology

This study took place at two private universities in the Klang Valley, Malaysia. Both universities are known to have a focus on innovative uses of technology in teaching and learning. A qualitative research method, semi-structured interview was adopted. Semi-structured interviews enable researchers to understand how social media technologies such as Facebook is integrated by educators into their teaching because the participants were asked about their expectations and experiences of using the technology as well as the pedagogical choices made when integrating the technology into teaching (Freeman 2014). The most important advantages of using interview are the wealth of detail and focused responses that it provides regardless of the difficulty in generalizing the data and the possibility of not getting the whole truth (Wimmer and Dominick 2014).

A semi-structured interview with three participants – two lecturers and a student – who used Facebook for teaching and learning in classroom education was conducted at their university campus on 11 and 14 January 2017 with an average duration of 46.8 min (ranging from 40.1 min to 53.1 min). The participants have voluntarily participated in the interviews, and they were able to answer the ten questions asked during the interview. The questions focused on their usage of technologies such as Facebook in higher education classroom, the advantages and disadvantages of Facebook use, and the perception on the effectiveness of using Facebook for teaching and learning in classroom education. The participants volunteered to share their experiences and perspectives of using Facebook as a teaching and learning tool in a Malaysian university classroom. The interviews were audio-recorded and further transcribed into 76 single-spaced pages of

transcriptions in English. The data from the interviews were content-analyzed using thematic analysis.

Findings and Discussion

In terms of Facebook usage in the Malaysian higher education classroom, findings indicate that Facebook is a popular networking site used by the lecturers and students as a teaching and learning and communication platform for formal classroom education. The lecturers of two private universities in Malaysia are using Facebook as a platform for students to ask questions about the subject, making announcements and online discussion. An active Facebook user such as a university student has used Facebook group for discussion among peers about lessons and assignment topics. The finding on how Facebook is used in the Malaysian higher education is consistent with the studies of Kabilan et al. (2010), Rasiah (2014), and Haque et al. (2015). Facebook is utilized as an online environment to facilitate learning and communication in the classroom and as “an avenue for a ‘formal’ academic discourse, whereby explicit assignments and tasks related to learning... could be integrated” (Kabilan et al. 2010, p. 185). It is also used for communication and announcement purposes due to the fact that Facebook is a medium suitable for making announcements (Haque et al. 2015) and useful for managing large classes (Rasiah 2014).

When the lecturer and student participants are asked why they choose to use Facebook for classroom education, the lecturers highlighted that opening a Facebook account is free of charge; it is easier and faster to use Facebook to communicate to students, especially to large group of students; it allows lecturers to feel connected to their students; there is more and better interaction with students; questions about the subject by students were not posted directly to the lecturer but to the class itself which encourages social learning; no constraint of time on Facebook as a way of consultation between educators and students; and students are always on Facebook with their friends; therefore, immediate response can

be garnered. These responses reveal the increased use of social media tools such as Facebook for teaching in classrooms by educators and faculty professionals because they see the potential of integrating social media technology to their teaching practices (Seaman and Tinti-Kane 2013).

The student on the other hand claimed that Facebook is becoming common as university students are often on Facebook and they have easy access to Facebook. Besides, students are more likely to read information and material posted on Facebook compared to the university LMS. The student also asserts that it is easier to share knowledge with others on Facebook, whereby all can learn. It is evidenced that students as active users extensively share information on Facebook (Abdulahi et al. 2014) and use Facebook to create, engage, and share existing or newly produced information between lecturers and students and among students (Lee et al. 2015) as well as use it as a tool of relaxation and entertainment in between their study during the university and college days (Kashif 2013).

The findings further support prior literature that Facebook offers benefits in the aspects of student learning experiences (Abdul Rahman and Mohd Amin 2014) and student engagement (Sim et al. 2014; Haque et al. 2015), complementing the current teaching and learning practices (Hamid et al. 2011) and enhancing academic performances (Helou and Ab. Rahim 2011; Al-Rahmi and Othman 2013). The use of Facebook could be explained through the Uses and Gratifications Theory because individuals actively select specific media outlets to satisfy specific needs (Katz et al. 1974, as cited in Ifinedo 2016). Lecturers and student of this study have selected to use Facebook for educational purposes could be motivated to fulfill their needs for information exchange, conformity, socializing, entertainment, passing time, and improving social knowledge (Phua et al. 2017).

In assessing the perspectives of the lecturers and students on the impacts of Facebook for teaching and learning in classroom education as addressed in research question 2, all participants express an optimistic view. For example, one of the lecturers looks at Facebook as a positive

teaching and learning tool because Facebook enables instant feedback. He argues on how students interact in Facebook is a sign of how well the cohort as a whole is going to perform in the final examination; if those cohorts are active, result is excellent. Another lecturer has used Facebook for online discussion, and she discloses that students are more vocal when they are on Facebook group, even students, who are very quiet, dare to speak out when compared to having a discussion in a physical classroom. These perspectives of the lecturers support the studies of Helou and Ab. Rahim (2011) and Ng and Maniam (2015), in which social networking sites have more positive impact on students' academic performance (Helou and Ab. Rahim 2011), in which the use of Facebook group discussions had significant effect on their performances (Ng and Maniam 2015). Therefore, Facebook has gained a unique position as a learning technology for educational purposes because Facebook group is created for managing educational content and it provides a conducive environment for student interaction (Ahern et al. 2016).

Nevertheless, the participants also acknowledge some setbacks of using Facebook for classroom education. The negative parts of it are as follows: the small fractions of contributors during online discussion; Facebook is a public domain causing the possibility of having outsiders or general publics who are not registered student to be in the group; distractions on teaching and learning practices; too reliant on a single technology; risk of plagiarism and privacy; and the overlapping between work and school with personal matters on Facebook. For example, the student agrees that distraction is one disadvantage of using Facebook for classroom education; however, she commented that distraction arises regardless of using Facebook or any other platforms. Another disadvantage of Facebook use in higher education reported in prior research was the privacy issue (Smith 2016). Despite privacy being the top of the list of concerns (Seaman and Tinti-Kane 2013), when the student was asked about privacy as a limitation of using Facebook,

she claims that it is not a concern for her because she is able to manage her social media account and she is conscious about what to click, what to put on, and how it will reflect on herself. It is noteworthy that the expression on both positive and negative impacts of Facebook use in Malaysian classroom education validates Smith's (2016) conclusion that social media is a double-edged sword that potentially helps and hinders university teaching and learning.

Lastly, the participants provide their views on the uses and impacts of using Facebook for teaching and learning in Malaysian university classroom. The first lecturer explains that when students are using Facebook, they can remain anonymous, but not faceless. He added that students feel safer this way to ask and respond to a question on Facebook, which becomes a good way for lecturers to assess student learning. The other lecturer agrees that social learning can be encouraged through Facebook discussion because students do not have to wait for the lecturer to respond but among themselves they are learning together. In addition, she implies that she will continue using Facebook to allow students to learn what is supposed to be posted and not. Nevertheless, both lecturers warn that Facebook is not a replacement for missing classes because it is just a supplementary tool, not the end-all tool. According to Haque et al. (2015), Malaysian students perceived Facebook as an alternative learning tool in the Malaysian higher learning institutions.

Additionally, the lecturers reveal that students are reluctant to use their university LMS for learning and communication purposes due to students' comfortability on Facebook and the Facebook interface is more interesting and exciting than their university emails or LMS. Importantly, both lecturers and students acknowledge the positive impact of Facebook on students' academic performances especially the usefulness of Facebook group for assignments discussion. The student discloses that Facebook group discussion is effective and helps in student learning because Facebook brings the learning experience outside from the classroom. A similar pattern is

evident in existing studies which indicated that Facebook brings benefits in students' learning experience as a platform for online discussion (Abdul Rahman and Mohd Amin 2014), in particular Facebook groups are used by students for creating discussion for assignments through the group posts (Al-Bahrani and Patel 2015).

Despite the benefits of using Facebook in higher education and the ubiquitous usage by students, one study claimed that teachers are hesitant of promoting the use of Facebook in the classroom (Raman et al. 2014), yet both lecturers of this study disagree. The lecturer participants are positive in using Facebook group because they perceive Facebook to be a safe environment for students to learn and they are able to cast a wider net to reach a bigger audience. Rasiah (2014) in her study concluded that Facebook is perceived as an innovative and effective tool in a student-centered learning environment because it enhanced students' engagement and learning experience (Rasiah 2014).

Conclusion

In this study on the use of Facebook in Malaysian higher education classroom, the goal was to look at the use of a social media technology – Facebook – for teaching and learning, and to explore the perception of lecturer and student in considering Facebook for effective classroom education. The findings suggest that the pervasive use of Facebook especially by university students has led to classroom use, and to feel connected to students and instant interactivity are the precursors to technology adoption by the lecturers. Besides, the findings of this study demonstrate similar outcomes with Freeman's (2014) study that the impetus for faculty members to use Facebook as a tool in their classrooms is distinctly pedagogical and not technological. The findings for both research questions concur with the research of Hamid et al. (2011); Hamat et al. (2012); and Ahern et al. (2016) that Facebook has a unique and powerful position to transform teaching strategies as well as the potential to

enhance and improve student learning (Ezell 2016). Thus, this study provides an empirical evidence that complements prior literature on the uses and impacts of Facebook in Malaysian higher education. The participants further recognize and value the benefits of using Facebook for teaching and learning in higher education classroom; hence, this study supports the earlier claim of the pedagogical rationale for using social media technology in classroom education. This study concludes that using Facebook is an opportunity for effective teaching and learning practices in Malaysian higher education classroom.

Introduction

The *Introduction to Programming* is an important field and at least one course with this or a similar title exists in all Computer Science (CS) and Information and Communications Technology (ICT) bachelor studies (Moritz and Blank 2005). A programming language selected for such a course should provide a notion in which to express algorithms, techniques, and data structures and focus on teaching programming and acquiring programming skills (Goosen et al. 2007). Computer science is a theoretical, as well as a practical discipline, and usually it deals with the science of computation, art, and craft. So, it is extremely important to learn an appropriate programming language (PL) in the first course in computer science.

Different factors and concerns (Ali and Smith 2014) influence the choice of the first programming language (FPL) for CS and ICT studies, and it is extremely important to differentiate key features of a language in the educational context. This is particularly valid today when we face dynamic evolution in the contexts and impact of ICT on individuals with the advent of Internet of Things, smart technology in virtually any corner of everyday life, as well as virtualization and cloud technology in the backend of ICT systems. The choice of the FPL in CS or ICT undergraduate studies can also be affected by previous experience of the learners which may vary significantly (Strong et al. 2017). The factors that influence the choice of the FPL are driven by didactical and pedagogical issues, business and technology development, as well as regional requirements, trends, and issues. Nowadays, for ICT teachers, it may seem that the choice of the FPL is a long-resolved matter. Even non-ICT teachers believe that it is obvious which language to use for teaching programming at bachelor studies. Therefore still there are a lot of papers that seriously consider this problem. Still the majority of teachers of programming topics are in dilemmas which programming paradigm and language to choose as first (Aleksić and Ivanović 2016), as this decision is considered to have a strong impact on later courses and finally on the development of a programmer.

During the history of developing numerous programming languages, some important programming paradigms have been recognized: imperative, object-oriented, functional, and logic. At the majority of universities in ICT curricula, the first two paradigms are still predominant though the functional paradigm gains on importance as the functional features are available and widely used in many of today's mainstream languages. Some teachers like to teach the most popular PLs but there are numerous possible measures of language popularity like: Most widely used? Most jobs offered for the knowledge of the particular language? Most lines of code existing in the language? And so on. Another problem connected to the popularity of programming language appears: Is the popularity of a language, a guarantee of its suitability for teaching programming concepts? Based on the above mentioned, it is clear that it is not possible to propose and select the best language for all situations.

In the last two decades with the appearance and intensification of use of some particular languages again a lot of debates appeared focusing on the choice of the FPL. Should teachers teach C, Java, C#, Python, Perl, Scala, JavaScript, or something else? Some authors plead that if the choice of a language is a key point then teachers are on the road to failure already. More and more institutions adopted Java in their introductory programming courses the last years but more recently Python is getting more and more popular. Nevertheless there is no universal satisfaction with a particular decision. As the choice of the FPL for ICT education is not an easy task, teachers have to be aware of this and continuously reevaluate language choice for their introductory courses.

In this entry, issues that are related to the role and choice of the FPL in introductory programming courses are presented. These issues are presented in the context of the relevant literature and the experience of the authors as well that have been teaching introductory programming courses for several years in three different Higher Education European Institutions: the University of Macedonia in Thessaloniki, Greece; the Masaryk University in Brno, Czech Republic; and the University of Novi Sad in Novi Sad,

Serbia. The rest of the entry is organized as follows. In section [“Goals and Syllabus of a Typical Introductory Programming Course,”](#) the goals and the syllabus of a typical introductory programming course are presented along with a short description of the introductory programming courses offered at the aforementioned institutions. In section [“Review of Research on the Effects of the First Programming Language,”](#) a review of the research carried out the last decades on the effects of various programming languages utilized as FPL in Higher Education Institutions around the world is presented. This is followed by a brief presentation of teachers' perspective on the choice of the FPL in section [“Teachers' Perspective on the Choice of the First Programming Language.”](#) More specifically, the main criteria that affect the choice of the FPL as recorded in the literature are briefly presented along with the factors that affected the choice of the FPL throughout the years in the authors' institutions. In section [“Students' Perspective on the First Programming Language,”](#) the perceptions of students from the aforementioned Higher Education Institutions regarding the FPL are presented based on a specially designed survey. The entry concludes with some remarks regarding the role of the FPL in introductory courses and some remarks regarding its overestimated impact on the success or failure of students in introductory programming courses. It is clear that the choice of the FPL is important but other important factors, such as the exploitation of Education and Information Technologies and generally the teaching approach utilized, should be taken seriously into account.

Goals and Syllabus of a Typical Introductory Programming Course

Most instructors agree that the main learning goals and outcomes of the FPL course are to support students in:

- Developing an algorithmic way of thinking and reasoning
- Acquiring problem solving skills

- Learning and applying the main programming concepts that exist in nearly every programming language, such as variables, control structures, strings, functions, and arrays
- Learning to design and code simple algorithms
- Learning to use contemporary programming environments for implementing and debugging programs
- Acquiring good style programming habits

Emphasis is not given on the details of the specific FPL, but on concepts and skills considered necessary for further learning other programming languages, either in the context of some other programming courses or studying them alone. Moreover, the aforementioned skills are the first skills that have to be developed in terms of employability and research in the ICT field.

As already mentioned, various programming paradigms or techniques exist nowadays, but the two most utilized in introductory programming courses are the imperative and object-oriented programming paradigms. No matter what the selected programming paradigm is, an introductory programming course usually deals with fundamental programming concepts, such as: data-types, variables, sequential structures, selection structures, repetition structures or loops, functions/methods, strings, arrays, manipulation of text files, and so on.

Our institutions have adopted the “imperative first” approach in the past based on C-like and Pascal-like languages for teaching the FPL. Recently new languages have been adopted which will be reported in the rest of the entry.

The University of Macedonia, formerly Department of Technology Management, which has merged with the Department of Applied Informatics, uses the imperative programming paradigm and the C language for the introductory programming course (since 2004) taking into account various didactical and pedagogical issues recorded in the literature (Xinogalos 2016). Specifically, students’ difficulties with the various programming structures as recorded in the literature and the course are taken into account for preparing the educational material utilized in it, a

pseudo-language in students’ native language is used for implementing the algorithm solving a problem prior its implementation in the programming language, and various forms of ICT are utilized for supporting the teaching and learning of programming. The Department of Applied Informatics uses C as the FPL for several years now, while its predecessor was Pascal. The Computer Programming course taught at the Department of Technology Management covered the following fundamental imperative programming concepts: primitive data types, variables, control structures, functions, arrays, strings, pointers, and text files. Currently, the Procedural Programming course taught at the Department of Applied Informatics covers moreover structures, arrays, and files of structures. This introductory programming course is followed by an object-oriented programming course based on Java.

Masaryk University, Faculty of Informatics, is a research and higher educational institution established in 1994 as the first educational institution in CZ primarily focused at computer science and IT. Since its foundation, it used Pascal as the first imperative programming language together with Haskell as the first functional paradigm language. Since 2011, the imperative programming language has been changed from Pascal to C with an alternative Python-based. Starting from 2016, Python entirely replaced the C-based course as the introductory one. The introductory programming course based either on C or Python have in principle the same didactical goals but slightly different techniques to attain them. The C-based introductory course followed a more traditional approach derived from the older Pascal-based introduction to programming course. The main aim of the course Introduction to Programming using C was to introduce students to basic principles of computer problem-solving. At the end of this course, students should be able to: design an algorithm to solve a given problem; code an algorithm in the C programming language; and debug a created program. The topics included basics of I/O functions, expressions, variables, basic statements and control structures, decomposition into functions, data types, and basic algorithms, such as numerical

and text processing algorithms together with some theory of algorithm analysis (correctness, efficiency). After completion of the Introduction to Programming through Python, students are expected to understand and apply basic constructs of programming languages, such as conditions, loops, functions, and basic data types, and will master several basic algorithms and techniques (sorting, searching, recursion, and some fundamental use of the turtle graphics). In general, the C-based course followed rather a “bottom-up” approach building the solution from basic elements upwards while the Python one is more “top-down,” progressing from motivation and problem to the coded solution. Recently (from 2018 onwards), Masaryk University study programs will face another change leading to coverage of (abstract) object-oriented concepts in a separate course to be followed with Java, C#, or C++ mainstream object-oriented language courses.

The University of Novi Sad, Faculty of Sciences used Modula-2 as a typical language designed for teaching programming purposes until 2015. The introductory programming course for computer science studies based on Modula-2 covered the basic concepts of the imperative programming style (primitive data types, statements and control structures, procedures, abstract data types, and recursion). Teachers’ opinion, based on experience spanning multiple decades, is that good educational programming languages (like those designed by Niklaus Wirth) are the most suitable to explain the aforementioned programming concepts to first year students. Modula-2 satisfied most of the desirable educational premises: most of students have pre-knowledge of Pascal so Modula-2 was convenient for them; it offers clean and well-structured features; it is also good for teaching other classical techniques and algorithms. However, in the last years, there was a constant pressure from different sources (like local companies, competition with other faculties with similar study programs, students, their parents, or other colleagues) to change the language used in the introductory course. So in 2016, a decision to teach basic programming concepts relying on Java was made, using an imperative-

first approach and just shortly mentioning objects at the end of the course.

Review of Research on the Effects of the First Programming Language

The choice of the first programming language has been a controversial issue for several decades. Nearly everyone agrees that the FPL is important and affects students’ subsequent education on programming. The importance of the FPL has resulted in extended research regarding the effectiveness of various programming languages and paradigms when used for an introduction to programming (Farooq et al. 2014).

Several studies focus on presenting the results of making a transition from one programming language to another in terms of a more suitable FPL. Next, relevant studies are presented in ascending chronological order with the aim of studying how the landscape on FPL has changed as years passed.

Radensky et al. (1988) report on their positive experience of using, at the time popular programming language Ada, as a FPL. The authors consider Ada to be more appropriate than Pascal and Modula-2 as an FPL and state that students are able to learn Ada easily and quickly. Moreover, students appreciate the advanced features of Ada and write more sophisticated programs. However, these are all based on subjective evidence and later Ada did not appear as widely used language.

Skublics and White (1991) report on their experience of moving from Pascal to Smalltalk. The main reasons for this decision were the simpler syntax of Smalltalk and the fact that it supports more the notions of data and procedural abstraction, encapsulation, and modular programming, as well as the fact that it supports the teaching of concepts prior to their implementation. Students’ grades in the revised course were compared with those of previous years when the course was based on Pascal and no significant difference was recorded. A questionnaire for recording students’ opinion for the course was also used; however, the small number of respondents (14) limits its importance. Students with

prior knowledge of programming stated that they had difficulty in their transition to the object-oriented paradigm. Another problem reported was the extended size of the class library.

Hitz and Hudec (1995) report on their unexpected positive experience on moving from an educational language to a conventional language used in industry. Specifically, the authors based exclusively on didactical considerations used – starting back in 1974 – Fortran, PL/1, Pascal, and Modula-2. Although they considered both Pascal and Modula-2 successful for the purposes of the course, they decided in 1992 to move to C++ in order to satisfy students' willingness to learn a language they would afterwards use in their studies and the market. Object-orientation and inheritance were not taught. No significant difference in students' performance was recorded, while students' feedback was positive. However, no formal instrument was used for investigating students' feedback.

As shown from the last two studies, at some point the research on FPL started to focus in the programming paradigm supported by the FPL. Brilliant and Wiseman (1996) used a survey regarding “the first programming paradigm and language dilemma” that was sent to Computer Science Departments at 145 Universities and received 45 replies. This survey investigated: the procedural paradigm and the languages Pascal, Modula-2, Ada, and C; the object-oriented paradigm and C++; and the functional paradigm and Scheme. Although, Ada seemed a good choice at that time, there did not seem to be a paradigm that offered significant advantages for the first programming course, while students seemed able to move to another paradigm with reasonable ease. However, other studies conclude that students face more difficulties during their transition from procedural programming to object-oriented programming and not vice versa (Decker and Hirshfield 1994; Hadjerrouit 1998a; Tempte 1991; Wick 1995).

As expected, this controversy between paradigms and languages was intensified with the advent of Java. Several papers were published reporting the advantages and disadvantages of Java as a FPL, as well as experience on using it in introductory programming courses. Hadjerrouit (1998b) reports on the experience of moving from

Simula and C++ to Java as a FPL in order to take advantage of object-orientation, concurrent programming, and its combination with the World Wide Web. It turned out that Java is not as easy as expected as a FPL, but it is also clear that it is necessary to incorporate it in the CSE curriculum. Several years later, Jabłonowski (2007) also reported on the great advantages of Java and at the same time its inadequacy as a FPL in comparison to Pascal or Smalltalk for instance. In a contemporary study, Farag et al. (2013) compared the effectiveness of an online introductory course based on C++ (control group) and Java (experimental group), respectively. No statistically significant differences were recorded for the two groups neither in terms of students' achievements nor in terms of satisfaction. Duke et al. (2000) stress out that object-orientation and Java are important for attracting students at universities. However, adopting Java as a FPL is just the first step that offers great opportunities for changing the way of teaching: adopting a problem-based approach; allowing students to work independently on their own pace; applying an inverse curriculum adopting object-orientation from the very beginning.

On the other hand, Ivanović et al. (2015) concluded that the choice of the FPL does not matter if students' performance at the course is used as the only criterion of suitability of the language. The authors presented their recent experience in changing the first programming language from Modula-2 to Java. The main idea was to try to discover if there are any significant differences in students' success between the most recent generation taught in Java, and several previous generations taught in Modula-2. Since there were not many other significant factors distinguishing the generations, they concluded that statistical analysis of collected scores and grades could provide insight into the effects of the change of language. Comparisons involving two nonparametric statistical tests showed that there are no statistically significant differences between the considered generations with respect to success in passing the exam.

For several years now, Python has come to surface as a FPL (Dierbach 2014). Sanders and

Langford (2008) studied students' opinions of Python as a FPL using a survey. Twenty-eight students with no prior programming experience and 27 students with some prior experience completed the survey. Both groups consider Python suitable as a FPL; however, some students with prior programming knowledge are reluctant to move to new languages. Leping et al. (2009) analyze the reasons for deciding to move from Java to Python, after a small-scale experiment on using Python as a FPL with 25% of the students. Python is a multi-paradigm language with a simple and clear syntax, while its popularity in the private sector is growing. Yadin (2011) carried out an action research with the aim of reducing the high dropout rates of students after introductory programming courses. Using Python as a FPL was an important factor, since its simple syntax helped students concentrate on problem solving and algorithms. Other contributing factors were using a visualization environment (microworld) and individual assignments. These factors in combination reduced the failing students by 77%.

So, the most popular programming languages in academia nowadays include C/C++, Java, and recently Python with significantly less represented alternatives ranging from specialized languages such as Matlab to C#, Haskell, PHP, or ECMA Script (Rabai et al. 2015). One of the reasons for the popularity of Python which contributes to its growing use is its multiparadigm approach (procedural, OO, and functional) being gradually more important to reflect in the selection of FPL. Due to fast growing popularity of powerful frameworks and easy web, cloud, and IoT development, another language – ECMA Script – is getting more popular also as a FPL. It is valid particularly for informal learning where developers can “learn by doing” when working usually in a team of more experienced developers.

Teachers' Perspective on the Choice of the First Programming Language

Educators and researchers agree that different factors and concerns (Ali and Smith 2014)

influence the choice of the FPL, as well as that the selection of the FPL has to be reconsidered from time to time based on both didactical/pedagogical issues and technological trends. The literature on this issue falls mainly into two categories: characteristics that a FPL should have; and criteria for selecting a FPL.

A typical example of a paper making suggestions for an ideal FPL is that of Kaplan (2010). Kaplan makes the following suggestions for an FPL in order for it to promote success in creating new programmers: it must support the teaching of the foundational concepts of computer science; it must enable the novice to learn the aforementioned concepts without interference from the details of the programming language; the feeling of competence and liking the practice of programming should be cultivated; and it should incorporate some of the notions of problem solving by design and support the transfer of an algorithm to the programming language. It is clear that these features are usually present in the so-called educational programming languages.

When it comes to selecting an FPL, the most complete list of criteria that could be taken into account is provided by Parker et al. (2006). The complete list of categories of criteria and the specific criteria falling in each category is presented in Table 1. Assigning of weights to each of these selection criteria based on their relative importance in the selection process can help in scoring various potential FPLs for an introductory programming course and making an informed choice.

When it comes to our institutions the factors that have influenced mostly the choice of the FPL, more or less, are the following: the popularity of the PL in industry; feedback from industry partners; programming languages used in competitive study programs; students' and their parents' concerns with respect to employability; the needs of the research labs at the Faculty; availability of good quality development tools and didactical material for the PL; and community support. However, the most important factor for selecting or changing the current FPL are its educational aspects or at least the ability to support students in

First Programming Language in Introductory Programming Courses, Role of, Table 1 Criteria for selecting an FPL (Parker et al. 2006)

Category	Criteria
Software cost	Reasonable financial cost for setting up the teaching environment Availability of student/academic version
Programming language acceptance in academia	Academic acceptance Availability of textbooks
Programming language industry penetration	Language's stage in life cycle Industry acceptance Marketability (regional & national) of graduates
Software characteristics	System requirements of student/academic/full version Operating system dependence Open source (versus proprietary)
Student-friendly features	Easy to use development environment Good debugging facilities
Language pedagogical features	Ease-of-learning basic concepts Support for safe programming Advanced features for subsequent programming courses
Language intent	Full-featured language (versus scripting) Support of web development
Language design	Real or customized Support for target application domain (such as scientific or business)
Language paradigm	Methodology or paradigm Support for teaching approach (function first, object first or object early)
Language support and required training	Availability of support Training required for instructors and support staff
Student experience	Anticipated programming experience level for incoming students

F

learning the FPL with specially designed educational programming environments and tools, as well as with applying teaching approaches that have proven to be effective for teaching and learning programming. In any case, the selection of the FPL is usually based on the proposals from the instructors of the corresponding courses and has to be carefully justified in order to be approved by the academic council that is responsible in each institution (such as Faculty assembly, Chair of the Faculty and so on).

Students' Perspective on the First Programming Language

In order to investigate what students think and how they perceive the introductory programming courses and the programming languages used in their context in our institutions, a questionnaire

survey (Xinogalos et al. 2018) has been carried out. The most important information for this study is presented in Table 2.

The main conclusions regarding the cognitive capabilities of the C and Pascal groups and mainly their perceptions on the FPL can be summarized as follows:

Cognitive Capabilities of the C and Pascal Groups

The students learning the basics of programming in Pascal-like languages possess the same cognitive characteristics as the students learning the basics of programming in C-like languages, in terms of their abilities to theoretically understand structures of imperative programming style and develop algorithms for solving programming problems. More specifically, students from both groups perceive the difficulty to theoretically understand structures of imperative

First Programming Language in Introductory Programming Courses, Role of, Table 2 Information for the study on students' perceptions for the FPL

Participants	90 students from University of Macedonia, Greece 87 students from Masaryk University, Czech Republic 111 students from University of Novi Sad, Serbia 288 students in total
Questionnaire	27 questions separated in two parts <i>Questions of the first part:</i> Content, difficulty, quality, organization, and contribution of the introductory programming course. <i>Questions of the second part:</i> Difficulty of learning the programming language used in the introductory programming course; installing and using related programming environments; solving concrete programming problems in that language; students' abilities to theoretically understand programming structures and conceptualize algorithms for solving programming problems. <i>Five-point Likert scale was used:</i> Not at all (1) /slightly (2) /averagely (3) /much (4) /very much (5).
Classification of students in groups	Students were classified in two groups: (1) students that learned basics of programming in a C-like programming language (2) students that learned basics of programming in a Pascal-like programming language <i>Group 1: C or C-like as an FPL</i> - 90 students from the University of Macedonia (C was used as an FPL) - 82 students from the University of Masaryk (C or Java was used as an FPL) - <i>Total:</i> 172 students. <i>Group 2: Pascal-like as an FPL</i> - 111 students from the University of Novi sad (Modula-2 was used as an FPL) - 5 students from the University of Masaryk (Pascal was used as an FPL) - <i>Total:</i> 116 students.
Statistical analysis	For each Likert-type question from the first part of the questionnaire basic descriptive statistics of students' responses per institutional group were computed: The median (the central tendency of answers), and inter-quartile range (IQR, a measure of the variability of answers expressed as the difference between the third and the first quartile). Nonparametric tests were used for comparing the opinions of the two groups of students in relation to the difficulty of learning programming. The ultimate goal was to determine which language class is more appropriate for introductory programming courses from students' perspective.

programming style as easy, while understanding of programming problems and conceiving an algorithm for a particular problem are perceived as activities of medium difficulty.

Installing and Using Programming Environments

Based on the results of the questionnaire there are no statistically significant differences between students from different groups with respect to the difficulty to install programming environments that are used in their introductory programming courses. However, a statistically significant difference was recorded in terms of using the programming environment that is perceived to be more difficult for the C group.

Difficulties in Learning a Programming Language and Using It for Problem Solving

There are no statistically significant differences between the two groups of students with respect to the degree of difficulty in learning the syntax and semantics of the introductory programming language, implementing an algorithm in the language, and correcting syntactical and semantic errors in their own programs. All the aforementioned tasks are characterized as easy. On the other hand, problem decomposition into functions/procedures and finding semantic errors (bugs) in programs are perceived by both groups as activities of medium difficulty.

Since the compared groups of students have the same cognitive characteristics, it can be

finally concluded that the choice of the introductory programming language does not have a deep impact on difficulties that novice students may experience when learning the basics of programming.

Of course, it is important to note that the aforementioned results regarding students' perceptions on the FPL were recorded in the context of three different introductory programming courses that were positively evaluated by students in relation to their content, organization, and quality. More specifically, the students that participated in this study (based on their replies in the questionnaire utilized):

- Considered the contents and the balance between the theoretical and practical aspects of all three courses as highly appropriate.
- Evaluated positively the quality, organization, and contribution of the introductory programming courses they attended.

It seems that the FPL is not the most important factor for students learning the basics of programming. It is the overall quality of the course and the instructors that make the difference. This might explain the results of similar studies reviewed in section "[Review of Research on the Effects of the First Programming Language](#)" that showed no statistical difference in students' performance when some instructors changed the FPL utilized in their courses. Whatever the FPL is, instructors have to work hard in order to make the learning of programming concepts easier for students.

Conclusions

The role of the FPL in introductory programming courses has attracted a lot of research interest for several decades and has been an issue of controversy for teachers and educators. Numerous articles have been published in the literature, and it is certain that many more articles on this issue are on the road. It is quite clear that ideally an educational programming language should be used for teaching an introductory programming course

utilizing an educational programming environment that supports students in dealing with the difficulties of programming that have been extensively studied in the literature. Several teachers believe that once a student has acquired solid foundations in a programming language, it is afterwards quite easy to move to other programming languages. However, when it comes to Higher Education, there are several factors that might not allow utilizing an educational language as an FPL, such as pressure from the industry and students/parents willingness to align with the software industry. Research has shown that utilizing a conventional programming language as an FPL in Higher Education is not as catastrophic as might be expected from the point of view of different educational stakeholders. The accumulated knowledge on students' difficulties when introduced to programming, the various advantages of utilizing Technology Enhanced Learning (TEL) approaches in programming courses (Educational Programming Environments, Intelligent Tutoring systems, Learning Management Systems), and generally teachers' informed choices on delivering a contemporary introductory programming course can alleviate the drawbacks of utilizing a noneducational programming language as an FPL.

Palmerston North, New Zealand

Synonyms

Distance education; E-learning; Flexible education; Online learning; Technology enabled teaching and learning

Introduction

Digital technologies can change major aspects of our lives including communication, socialization, and learning. The use of technology for learning in today's world may seem a relatively recent phenomenon. It may come as a surprise to learn that the use of technology in flexible and distance contexts is not new. Fields of study that encompass distance education, online learning, human-computer interaction, and computer-supported collaborative learning have all contributed to a rapidly growing body of research that seeks to understand the experiences and behaviors of learners and faculty in technology enabled learning environments. Research to date demonstrates that the effective use of digital technologies in distance and flexible contexts is a complex endeavor.

Distance and flexible learning has a rich history that dates back decades. Findings from this considerable body of research have led to new ways of understanding the learning process that are distinct from learning that occurs in place-based, face-to-face situations such as the traditional classroom or lecture theatre. This new knowledge, in turn, has resulted in new pedagogies and theories that help those teaching in flexible and distance learning situations to understand and address the needs of learners. What follows is a necessarily brief review of the generations of distance and flexible learning, notable frameworks, influential theories and pedagogies,

technological affordances that support distance and flexible learning, and challenges associated with flexible and distance learning.

Distance Learning

As the use of technology for learning has grown exponentially, the terminology to describe its use has multiplied. Terms such as distance learning, online learning, e-learning, and technology-enabled learning, are just some of the terms used to describe the application of technology in educational settings without necessarily defining exactly what each means. E-learning, for example, is a broad term frequently used to describe any type of learning environment that incorporates digital resources or that is technology-enhanced or enabled. The term has become so generic that it has lost much of its meaning. The net result is that there are multiple technologies and modes of learning encompassed within the e-learning domain. There is, however, general agreement that distance learning is a subset within the broad e-learning domain.

Distance learning refers to learning that takes place away from the actual physical classroom or campus. Distance learning has a range of potential benefits, primary among them is the ability to overcome the time and location limitations of traditional educational settings (e.g., classroom or campus). Consequently, it offers learners the flexibility to learn at their convenience in any location (e.g., home, office, school, university, café, etc.) in their own time, often at their own pace, without the requirement for face-to-face contact with a teacher. Another benefit of distance learning is improved equity of access. Individuals excluded from education in the past, due to geographic location, personal circumstances, financial constraints, disabilities, or lack of course availability, have more opportunities to participate (Moore and Kearsley 2012). Today, distance learning is generally equated with fully online learning – that is, learning that occurs entirely on the internet.

Flexible learning expands the choices available to individuals about what, when, and how they learn. The guiding principle of flexible

learning is learner choice over various aspects of their learning experience. Examples of flexibility include time, place, content, entry requirements, instructional approaches, learning resources, technology used, and communication channels. Flexible learning offers diverse approaches to learning and in doing so supports the needs and interests of learners. Technology use is a central part of flexible learning, but flexible learning encompasses more dimensions than technology alone. Other dimensions of flexible learning include pedagogy, implementation strategies adopted to introduce greater flexibility for learners, and institutional frameworks used to support the provision of flexible learning options across an organization (Collis and Moonen 2001). For the purposes of this entry, flexible and distance learning are considered interrelated with distance learning enabling and enhancing learning flexibility.

Generations of Distance and Flexible Learning

While it not the intention here to provide a detailed account of the history of flexible and distance learning, it is important to recognize that the technological innovations we see today extend knowledge developed from previous generations of distance education. Different generations describe the changes ushered in by various technological developments. The first three generations are frequently characterized as correspondence, broadcast (i.e., radio and television), and computer-mediated (Nipper 1989). While most scholars generally agree about the first two generations, the third and subsequent generations have different approaches. Alternative views of third generation distance learning include those that focused on the technology such as the telelearning model (Taylor 2001), whereas others took a more holistic view that encompassed a systems approach to distance learning (Moore and Kearsley 2012). Fourth and fifth generations of distance learning have also been suggested, linked to flexible learning, enabled via online delivery and aspects of intelligent digital technologies, respectively (Taylor 2001).

The emergence of the first generation of distance learning, correspondence study, involving the use of print-based materials, came about from the need for an educated workforce brought about by the industrial revolution. Factors that contributed to development of successful correspondence study programs included the development of new technologies such as the printing press, low cost pens, and the emergence of a publishing industry, as well as systems that supported the distribution of materials such as the introduction of an inexpensive and dependable postal service and efficient transportation systems (Sumner 2000). During this period, distance education providers emerged who saw correspondence study as a way of providing opportunities to those poorly served by traditional educational institutions.

The second generation of distance education, broadcast, grew out of the development of new communication technologies, advancement of print materials, better quality support services for distance students, and the founding of the Open University of the United Kingdom (UKOU) and mega (distance) universities. This generation did not exclude correspondence instruction, as the emergence of new delivery technologies often embrace those that precede them. However, the broadcast era predominantly involved the use of one-way technologies, namely radio and television broadcasts, along with audio and video cassettes and telephone communication (Sumner 2000). Associations established during this period include the International Council for Open and Distance Education (ICDE) and the Commonwealth of Learning (CoL).

Structured learning materials and predominantly one-way communication from the teacher to learners characterized the first and second generations of distance teaching and learning. Learning was considered an individual process with little, if any, social interaction. Learning models were influenced by behaviorist and cognitive learning theories with the main focus being the acquisition of knowledge (Nipper 1989).

Even though alternate views existed of third and fourth generations of distance learning, the common thread was the potential of conferencing

that added to the strengths of the previous generations. By the early 1990s, the availability of video conferencing, providing both visual and audio connections, allowed two-way, synchronous communication between faculty and students (Taylor 2001). With the advent of computer-mediated distance education, in particular the internet, came facilities such as email, bulletin boards, learning management systems and computer-mediated conferencing (CMC), asynchronous and synchronous, that provided the means for students to interact with faculty and other students in ways not seen in previous generations. Discussion occurred among scholars about whether the internet ushered in a new paradigm of learning because of new modes of delivery (adjunct, blended and fully online and distance), new learning domains (many-to-many communication, place and time-independence), new principles of learning (collaboration and accessibility), and new learning processes and outcomes (high levels of active learning, learner engagement and interaction).

Regardless of whether observed changes reflected a new learning paradigm or not, later generations saw a shift towards more flexible, interactive, collaborative, and constructivist approaches to distance learning. However, the developments of new technology were not solely responsible for the changing approaches to distance learning as progressively constructivist and social constructivist perspectives of learning have become influential and prominent (Anderson 2008b).

Newer generations of distance learning have continued to evolve. Part of the reason for this is that distinctions between traditional (classroom) learning and distance learning are disappearing, with similar technologies used to support learning in a variety of contexts including distance, face-to-face, and blended (a mix of the two) resulting in increased flexibility for learners. The shift towards openness, and the resulting flexibility, in courses, practices and resources that newer technologies can make accessible, have opened up many possibilities for learning to continue across the lifespan (i.e., learning that people engage in throughout their lives). New opportunities

encompass formal learning (e.g., learning that takes place in educational contexts such as tertiary institutions), nonformal learning (e.g., professional learning and development workshops), and informal learning (e.g., pursuing a hobby).

Recent examples of models of flexible and distance learning include MOOCs (massive open online courses) focused on large-scale learner participation that are open and available to anyone who has access to the internet. Platforms include Udacity, edX, and Coursera in the USA and FutureLearn in the United Kingdom, who have developed an extensive suite of offerings. OERs (Open Educational Resources) are any type of educational materials (e.g., textbooks, curricula, lesson plans, videos, assignments) in the public domain that are able to be freely used, copied, adapted, and shared. Examples include: the Massachusetts Institute of Technology (MIT) open courseware; the Kahn Academy, which provides thousands of videos covering a range of curriculum areas including mathematics, science, and history; and the OER commons, an open, curated digital public library platform. These examples (and there are many others) highlight a shift toward flexibility and availability that is increasingly afforded by new digital technologies.

Mobile technologies are also playing an important role in distance learning as they provide the potential to reconfigure and redefine the spaces in which people learn. Mobile learning has a number of characteristics that incorporate learning across time and locations; ubiquitous knowledge access; use of multiple devices; formal, informal, personalized, and social learning; blending of physical and digital worlds; switching between multiple learning activities; and the use of a range of pedagogical models (Wong and Looi 2011). These characteristics point toward increasing flexibility and personalization for learners.

Increasing use of data is the common characteristic of the current generation of distance learning. Learning analytics is an approach adopted by educators and institutions trying to improve student retention and learning experiences by using large amounts of readily available data. Analytics models examine large sets of data looking for patterns that can offer insight to learners, faculty

and support staff who have responsibilities for supporting learners. These models use data from various sources (e.g., student enrolment, demographics, achievement, learning management systems) frequently aggregating them in new ways in an attempt to understand past and present academic performance and to predict future performance (Liu et al. 2017). Insights gained identify students who are at risk of academic failure or dropping out as well as the development of feedback strategies and interventions to mitigate these risks. More recently, learning analytics are assisting the development of more personalized learning approaches with the intention of improving student outcomes.

What the above examples demonstrate is a rapidly evolving and changing landscape of learning generally and distance learning in particular. The potential of technology to promote learning opportunities has never been greater; however, the effective introduction of newer digital technologies into any learning situation is a complex endeavor. As Anderson (2016) argues, “it is imperative, therefore, to identify theoretical constructs to guide technology-enhanced interventions.”

Prominent Theoretical Models and Concepts

Distance and flexible learning has a history of educational theory adoption and development. Constructivist perspectives of learning, in particular the social, situated, and constructed nature of learning, have gained prominence in distance learning (Dyke et al. 2007). Characteristics such as mediation, internalization, cognitive apprenticeship, and distributed intelligence influence the design and development of many distance courses. Emphasis is on the development of online learning communities enabled by digital technologies, creating opportunities for interaction and collaboration through dialogue and discussion.

While it may not be unexpected to discover that well-known educational theories, such as constructivism have been adopted in flexible and

distance learning contexts, new theories and frameworks have emerged that focus on the unique characteristics of learning that occurs both temporally and spatially distant from the teacher and classroom. One of the most well-known is the theory of transactional distance advanced by Moore (2013b) in 1973.

Theory of Transactional Distance

Moore conceived the term *transactional distance* to explain the psychological separation, often experienced by learners, because of the physical and time separation between learners and faculty in distance learning situations. According to the theory, the relationship between the structure and dialogue innate in a learning task determines the degree of “distance” a learner experiences. Structure is associated with the design of a course and indicates the flexibility or inflexibility of adopted teaching approaches, objectives, assessment processes, and so on. Dialogue refers to the amount of interaction between faculty and learners and is associated with the communication medium. According to this theory, low structure and dialogue result in high transactional distance and vice versa. However, high dialogue and structure are difficult to achieve concurrently. While the original theory emerged before the internet was widely available, the idea of transactional distance still resonates with distance learners today.

In addition to structure and dialogue, transactional distance theory includes a third concept, learner autonomy. The larger the transactional distance (i.e., low dialogue and structure), the more responsibility is placed on the learner. Autonomy, in this theory, is synonymous with independence and self-directed learning. The transactional distance model does not suggest that autonomous learners do not need faculty but it does indicate that less dialogue and minimal structure is required when compared with less autonomous learners (Moore 2013b).

Learner Autonomy

Learner autonomy is a central concept in flexible and distance learning; however, the lack of an agreed definition has complicated understanding of what the term encompasses. Some argue that

learner control is a more comprehensive concept than learner autonomy as it addresses the confusion often associated with independence in distance education. Learner control focuses on the opportunities and abilities of learners to influence, and make decisions related to their learning (Anderson 2013). This requires a balance to be struck between independence (learners having the ability to choose freely without restrictions), power/competence (learners taking responsibility for engaging with the required learning), and support (resources, including faculty, available to learners). Support from the teacher enhances learner control rather than reducing it.

Other research has also influenced our understanding of choice, control, and autonomy in distance learning. Some concentrated on control as learner self-direction and identified two types, namely self-direction as: (1) an individual characteristic and (2) the amount of control a learner exerts over his or her learning trajectory. This distinction recognizes that autonomy is both an individual and situational variable indicating that the degree of autonomy a learner expresses can vary across contexts and situations (Anderson 2013). Dron (2007) subsequently developed a transactional control conceptual model. Transactional control focuses on choice and outlines the dynamics of transactional distance. In this model, control is a continuum from teacher control at one end to learner control at the other. Choices made along the learning path influences where a course or learner sits on the continuum. Structure equates to teacher control, dialogue with negotiated control, and autonomy to learner control. In addition to concepts such as independence, control, and self-direction, several studies have demonstrated the importance of learner autonomy, defined as an internal locus of causality and perceptions of freedom and choice over actions, from a motivational perspective (Hartnett 2016).

Community of Inquiry Framework

Another framework that has been influential in the development of understanding flexible and distance learning is the community of inquiry (CoI) framework (Garrison et al. 2000). According to the CoI model, effective learning occurs when

interactions consist of three core elements: cognitive presence, social presence, and teacher presence. Cognitive presence refers to the degree to which learners are able to construct meaning through communication; social presence is associated with the ability of learners to present themselves as “real” to other community members; and teaching presence relates to the design and facilitation of the learning experience including instructional management, the facilitation of knowledge development, and direct instruction. Teaching presence is not always the sole responsibility of faculty and can be adopted by learners who contribute their own knowledge and experiences to build understanding within the learning community (Anderson 2008a). Since the original development of the CoI model, its use and validation has been extensive. Cognitive presence, social presence, and teaching presence have been the focus of research interest.

Recent Theories

Newer theories have also emerged in recent times which have been referred to as “net-aware theories of learning” (Anderson 2016). Net aware theories attempt to understand learning in a connected world where specific affordances of the internet have resulted in abundant access to content and information, massive capacity for communication and the increasing use of autonomous agents, which automate the filtering, aggregating, and synthesizing of content.

One such “net-aware” theory of learning is connectivism (Siemens 2005). The theory of connectivism argues that learning occurs through connections made within networks and the capacity to know more is more important than current knowledge. Importantly, learning can reside outside of the learner within nodes of the network, including learning resources, machines, and other people. Facilitating ongoing learning requires the creation and maintenance of connections. Learning, through the lens of connectivism, is social and knowledge is constructed through interaction and dialogue.

Following on from “net-aware” theories, “network-centric” theories of learning have emerged. These include theories that focus on the network,

theories that focus on social-personal interrelationships and theories that address the design of the network. Connectivism is a well-known example of a theory that focuses on the nature of the network itself. Theories that address social-personal interaction center on the premise that given the changing nature of society and the resulting need for learners to engage in lifelong learning, individuals need to be self-determining in their own learning (Gros 2016).

With the rise of networked learning, heutagogy (the study of self-determined learning) has reemerged as an area of interest and study in the distance and flexible learning field. Essentially, learners are active agents in their own learning and are encouraged to take ownership of their own learning pathway supported by the affordances of web 2.0 technology. In this respect, “network-centric” theories reflect earlier distance learning theories.

Theories that focus on the design of the network generally attempt to provide a theoretical framework from which to consider personal learning environment (PLE) models. Essentially, PLE’s consist of web 2.0 tools and networked technologies that help learners control and manage their own learning. Theories that help describe the design of the network build on other theories such as connectivism.

This section has highlighted that the field of distance and flexible learning is rich in learning theory application and development, whose origin is traced back several decades. This richness is particularly true in contemporary times where the influences of the web and digital technologies are encouraging the emergence of new, network-based theories of learning that build on earlier generations of understanding.

Technological Affordances That Support Distance and Flexible Learning

The use of the internet and related technologies for flexible and distance learning requires approaches that capitalize on the affordances of those technologies. When done effectively,

learning experiences that overcome the challenges associated with distance learning, such as learners’ sense of isolation and issues of persistence, are evident (Moore 2013a).

The term affordance was developed to describe the possible actions or opportunities a particular environment or artefact provides to people (Gibson 1979) that can be inferred from visual or other information that is readily apparent. In other words, an affordance is a characteristic inherent within the object. More recently, the definition of an affordance was expanded to incorporate perceived as well as actual inherent properties of an entity that determine its possible uses (Norman 1988).

The term “affordance” has seen increasing use in education over the last decade or so, particularly in relation to digital technologies. The term has often been used in an attempt to identify and relate the attributes of various technologies to their potential value for learning. The affordance of “communication and interaction,” for example, is reflected in descriptions of web 2.0 (which denoted a second generation of capability encompassing participation and content development (a form of interaction) for educational purposes rather than just content consumption as was previously the case). One well-known affordance of the web is its communication, interaction, and collaboration capability. Examples of digital tools that encompass this affordance include wikis, blogs, and social networking sites (to name a few), which see increasing use in flexible and distance learning contexts.

The web 2.0 example may tend to suggest a kind of technological determinism that views new modes of communication and interaction as actively caused by particular forms of technology. In simple terms, the technology itself determines how humans communicate and interact. This kind of deterministic (one-way) view of technological affordances is somewhat simplistic. Hutchby (2001) offers a more nuanced position that technologies can be viewed as artefacts that “may be both shaped by and shaping of the practices humans use in interaction with, around and through them.” In other words, the affordances

of a technology are not necessarily fixed or predetermined (even if there exists a predominant or prescribed use) but can change depending on a variety of factors including the person using them, the situation, the expertise of the user, their background, and the social, cultural, or learning context.

What this essentially means is that technological affordances need to be considered as part of the learning environment as a whole, of which digital technologies are an integral part, rather than viewing technological affordances in isolation from the context in which they are being used. Another way to think about this is to view digital technologies as having potential affordances which can only be fully understood (and therefore fully utilized for teaching and learning purposes) in the context in which they are being used, taking into account factors that act to promote or constrain them. Furthermore, learners and faculty need to be able to perceive the potential affordances of the technologies and the learning conditions needed to support their expression. This is an important distinction because the actual affordances of specific technologies in distance learning contexts may differ to those in place-based situations for the same technologies.

Several frameworks attempt to identify and categorize digital affordances as they relate to learning. Examples include accessibility, diversity, communication and collaboration, reflection, multimodal and nonlinear, and immediacy. Affordances specific to social software use for learning encompass connectivity, collaboration, content creation and modification, and information aggregation (McLoughlin and Lee 2007). Mobile digital device affordances include responding to the user, handling information, collaboration, audience (access to) which, in turn, can support motivation (McFarlane 2014). It is clear from the different approaches that there are areas of overlap. Of note, is that all of the above identify collaboration as an important affordance of digital technologies.

Collaborative affordances have been further categorized in terms of collaborative opportunities to engage in joint tasks, communicate, share

resources, engage in collaborative learning processes, engage in co-construction, monitor, and regulate learning and find and build groups and communities (Jeong and Hmelo-Silver 2016). This discussion of the various types of technological affordances is by no means exhaustive. Other affordances include learner agency, creative thinking, design thinking, and personalized learning, to name a few. It is also important to note that new digital affordances are likely to emerge and existing ones change as digital technologies evolve and the uses to which learners and faculty put them change.

Interaction and Collaboration in Flexible and Distance Learning

Flexible and distance learning researchers and practitioners recognize the potential of collaborative affordances. A body of research has recognized the importance of online learning communities where opportunities for collaboration and interaction through dialogue and discussion are realized through the use of digital communication tools (Rovai 2002).

Four well-known types of interaction are learner-instructor, learner-content, learner-learner, and learner-interface interaction (Friesen and Kuskis 2013). Learner-instructor interactions are exchanges between learners and the teacher that focus on supporting the motivation and interests of learners. They also offer a feedback channel allowing misunderstandings to be resolved. Types of learner-instructor interactions include establishing learning outcomes, provision of timely feedback, information presentation, monitoring and evaluation of learner progress, facilitation of learning activities and discussions, and determining learners' needs.

Research exploring learner-instructor interactions have resulted in the development of facilitation guidelines (Rovai 2007). These guidelines include strategies for supporting learner motivation that incorporate design principles that integrate learner choice, learning expectations, and online community establishment. Outlining the purpose and relevance of online interactions to learners, making explicit connections to learning

outcomes, and providing appropriate support to encourage participation are further, important considerations.

With the increasing ubiquity of internet access, learners are able to choose from an enormous variety of content and resources. Learner-content interactions identify the intellectual processes that occur between the learner and resources linked to a module of study and are central to distance and flexible learning. Learner-content interactions are evident when learners access textual, audio, graphical, video, and virtual reality representations (Friesen and Kuskis 2013). To interact with content effectively, learners need the skills to access appropriate and relevant resources, which can require content curation from a knowledgeable person such as a faculty member.

Learner-learner interactions describe processes that occur between students studying together. This can include processes such as sharing information and thinking, working together to interpret and complete tasks, solving problems, and sharing opinions or personal insights. Digital communication tools provide distance learners with opportunities to collaborate and actively participate in knowledge co-construction via online discussions (Dyke et al. 2007).

Online communication occurs when learners and faculty use networked technologies to interact and exchange information via synchronous and asynchronous digital tools. Synchronous interactions such as those afforded by web-conferencing tools like Skype, Zoom, Connect, and Google Hangouts allow discussion in real time. Asynchronous communication tools offer more flexibility as they do not require participants to be simultaneously online and allow all community members to have input to a discussion by giving learners time to think and reflect before responding. Communication can occur in the form of text, video, audio, or a combination of these and frequently takes place within discussion fora such as the ones found in learning management systems.

For learners to participate and have positive interactions with peers, they require knowledge and skills to use technology effectively. This

includes having requisite prior knowledge and self-regulation skills. Even with the required skills, peer interactions in distance learning environments are complex and cover a range of intellectual (e.g., reviewing, conceptualizing), social, emotional, and instructional interactions (e.g., analyzing). Analysis of asynchronous peer discussion transcripts has led to a greater understanding of effective peer interactions in distance learning contexts.

The principal mechanism through which an online community is developed and maintained is interaction. Interaction between learners and the development of learning communities are crucial factors in the success or failure of distance courses (Rovai 2002). Developing a supportive network among distance learners can support motivation to learn, commitment to collaborative goals, support co-construction of knowledge, and is significantly related to perceived learning (Rovai 2002). However, developing a network is a complex endeavor. Interaction is an indispensable element of a supportive community but does not occur by providing access to digital communication tools. Class size, course structure, faculty availability, and group facilitation, learners' prior experience, social presence, and personal agency all affect student interaction and perceptions of feeling part of a distance community (Hartnett 2016).

Learner-interface interactions refer to a learner's ability to use the required technological tools to interact and communicate with the teacher, other learners, and the course content. Learner interface interactions mediate all other interactions (Friesen and Kuskis 2013). A relationship exists between a learner's beliefs in their ability to use the required technological tools to learn and their performance within distance learning contexts.

This section has identified that the adoption of constructivist principles that encompass the concepts of collaboration, interaction, and dialogue are important foundations in the development of successful distance learning communities. In the next section, attention focuses on some of the well-known challenges associated with flexible and distance learning.

Challenges Associated with Flexible and Distance Learning

A great deal has been written about the transformative nature of digital technologies, but issues remain, the most fundamental of which is the belief that the technological tools are the transforming influence in distance and flexible learning. This argument has existed in various forms over many years and results from the confounding of the technological tools used with the pedagogy embedded within the design of distance and flexible courses.

At an individual level, the issue of access and affordability results in digital exclusion of some students and can highlight social, economic, and cultural inequality. Retention rates in flexible and distance courses have also been a persistent challenge (when compared with similar face-to-face courses) over the years (Moore 2013a). Feelings of isolation, technical frustrations, lack of requisite prior experience, inadequate technical support, unwilling participation of faculty or students, lack of timely feedback, time constraints, other responsibilities, and low learner motivation are all factors that influence students' decisions to persist or not with distance learning courses (Allen et al. 2013). Furthermore, the size of the group, the formal nature of postings, the effort and stress that can be part of collaborative activities due to issues, such as differences in time zones and language, and study workload can leave students with negative impressions of distance learning (Hartnett 2016). Despite these challenges, meta-analyses of satisfaction research shows students only have a slight preference for face-to-face study compared to distance learning (Allen et al. 2013). Establishing clear learning goals and outcomes, choice and sequencing of content, learner engagement and motivation, interaction (learner-instructor, learner-content, learner-learner, and learner-interface), guidance and feedback strategies, technology access, and selection of technological tools are just some areas that require consideration to ensure well-designed courses meet distance learners' needs (Hartnett 2016).

Faculty, too, face their own challenges when teaching in distance and flexible learning environments. Some institutional leaders have considered distance and flexible learning as a way of increasing productivity and reducing costs, but evidence indicates that more time and effort is required from faculty (Shattuck 2013). Teaching in distance learning contexts requires ongoing learning involving the development of new knowledge, skills, and strategies that encompass both pedagogical expertise as well as technological knowledge. For this to be successful, timely, ongoing professional learning and development, offered at an institutional level, is required along with release time for faculty to develop and apply newly learned skills. In addition to institutional support and ongoing training, faculty participation needs to be recognized and valued at an institutional level. Well-designed institutional policies and procedures are also important as they can act as guidelines for faculty when engaged in course development and online teaching (Shattuck 2013). For example, the burgeoning availability of educational resources requires faculty to be familiar with copyright and usage rights in more depth than required in previous generations of distance education. This example highlights the need for specific guidelines for faculty who are not copyright experts.

Conclusion

This review has briefly explored the different generations of distance and flexible learning, notable frameworks, theories and pedagogies that have emerged, technological affordances that support distance and flexible learning, and challenges associated with flexible and distance learning. What of the future? One thing is clear: it will be different. There are technological advances on the horizon that are set to profoundly influence flexible and distance learning and learning more generally. Innovations such as virtual reality (VR), augmented reality (AR), and artificial intelligence (AI) are set to reshape the nature of learning. Although a crucial factor, it is easy to overstate

the role of new technologies in the development and transformation of flexible and distance learning practice. It is not simply a question of introducing the latest technology. Pedagogy and technology are interrelated and changing technologies will influence the scope and style of contemporary pedagogies. Therefore, distance faculty need to understand the implications of technology use, within the context of wider society, as they have an essential role to play in preparing learners for the future.

Introduction

Since the 1960s, there has been the development of the virtualization of hardware platforms (systems). This ensured simultaneous access to it for many users and operation systems. Today we can speak of the virtual systems independent from each other, in which virtualization of applications (or processes) takes place. It creates some “abstract environment” making virtualization independent of hardware. Currently a lot of special applications for education are developed. Virtual Reality serves as a learning tool. The current human education can be presented in different formats, which is considered in this work.

Virtual worlds in the formats of virtual learning embody abstract knowledge and concepts, quite specific “material” forms, and expressions. The work by Sánchez et al. (2000) presented this idea sufficiently.

The fundamental point, which scientists, pedagogues, and developers must take into consideration, is the idea that Virtual Reality in the human education process is not a passing fad but a universal technology. This technology is intended to improve the process of gaining knowledge, abilities, and skills by trainees. Besides, involvement of students in the virtual learning environment has a positive influence on the process of their socialization and motivational and cognitive sphere of their personal development. If we analyze virtualization of learning process, we see that there are more positive points than negative.

Some models of educational systems of Virtual Reality are presented in different studies in the sphere of informatization and electronic learning.

The works by Whitelock et al. (2000) describe exciting opportunities for users for entering new worlds using the Virtual Reality system. The experience of the practical use of Virtual Reality at school is described in the works by Lang (2004), Dipietro (2010), and Toppin and Toppin (2016).

Virtualization in mobile learning is described in the articles by Ikram et al. (2015) and Harley et al. (2016).

This article considers some formats of virtual learning, which have been used in theoretical and

practical training of university students. The developed formats have had a positive influence on developing the students' knowledge and learning outcomes. The described learning formats proved that virtual learning really broadens the scope of educating people of different social status and position, studying in different countries. Besides, some forward-looking formats of Virtual Learning are presented, working at which enables to improve the education process further.

Emergence of Virtual Reality: History and Survey

Ideas of Virtual Reality appeared as early as antiquity and fascinated many prominent people for most of humankind's existence. It is worth recalling Johannes Duns Scotus, a medieval Scottish theologian, philosopher, and schoolman, who asserted the existence of matter or its reality regardless of the form, which defined only the quality of physical being. The existence of "some" reality was also of concern to the monk Gaunilo from Marmoutier who in his book *In Behalf of the Fool* constructed an ontological argument for the existence of reality in our imagination. He invited his readers to think of the greatest, or most perfect, conceivable island. It is likely that no such island actually exists. However, his argument was the following: "We aren't thinking of the greatest conceivable island, because the most conceivable island would exist, as well as having all those other desirable properties. Since we can conceive of this greatest or most perfect conceivable island, then it must exist."

If at the time of Gaunilo these arguments seemed absurd, then today it is possible to create such reality using twenty-first century technology.

The idea of the very first human immersion in the artificial world belongs to Morton Heilig. In 1960 Heilig opened a cinema with special moving armchairs, different potpourri scents, speakers for playing back sound, and a special screen. Using all these in his cinema, Morton succeeded in giving spectators a sense of artificially created scenery such as a noise, a wind, and even some scents.

Heilig's construction gave start and the future to Virtual Reality.

The main problem of the twentieth century is the creation of the artificial world where a living organism can successfully coexist with the machine. Therefore there appears a human-machine interface.

From "timid steps" in the sphere of entertainment, Virtual Reality enters the process of educating and teaching.

Modern education is a distance education with a complex virtual training technology of teaching. The use of virtual education technology is presented in the works of the scientists who share their working experience in this field.

Education and Information Technology of the Twenty-First Century

The modern world is characterized by transformation of the modern society, in which computerization and informatization are integrated as key tendencies.

Introduction of modern information and communication systems (electronic mail, electronic teleconferences, electronic and information resources with text, visual, audio, and video information) and Virtual Reality technology (Daydream, Vive VR, virtual game technology) turns the latter into a mass product. Virtual Reality as an abstract phenomenon in some way and at the same time having a certain product is widely used practically in all the spheres of the human society. The application of modern information and communication technology (ICT) and technology of Virtual Reality to the theory and practice of higher education creates objective conditions for the interactive communication of international education participants using LMS and for the development and introduction of the system of the professional training of specialists in the virtual educational environment of a higher education institution (Kerimbayev et al. 2017).

Humanity is progressing and is on its way towards technological progress. It is increasingly difficult for the human memory to keep a growing

body of information, knowledge, and skills. While information changes a new knowledge of changing abilities and skills needed for one or another sphere of human activity is required. It implies the need for such form of education, which would help gain these skills while remaining in main professional activity, or even creating conditions of virtual assistance and simulation, and immersing in the specific environment providing with learning “at a distance” with the effect of being present.

Distance learning is used to provide with such form of knowledge transfer. However, just transmission (postage or using Internet technology) is not sufficient today. Distance learning is enriched by new tools today.

Modern online education uses interactive video, gamification, applications, and explanation of the material in the format of scenarios, simulations and stories, and ready samples with the application of various interactive online teaching methods. Other important technological services are widely included in the education process, such as artificial intelligence, updated Virtual Reality, robots, and voice technology. Voice assistants participate in the learning process and can resume basic concepts of a lecture and carry out a session in the form of “question-answer” before the examination; with their help students can receive notifications of updates or their home tasks.

The distinctive feature of the modern higher education is emergence of virtual universities. The educational process of such learning format widely uses digital technologies. Online learning often becomes a contemporary alternative when students cannot be present at a lesson because of some reasons, for example, a heavy snowfall or a severe frost.

In a context of technological innovations and labor market demands, there arises a necessity of improving prior knowledge, gaining new abilities and skills in the professional environment. Sometimes one needs not a long academic instruction but a short and at the same time proper education providing the required knowledge and abilities. This implied the process of “microfication” of online education, which implied the duration of

training sessions, as well. Here there arises the problem of the teaching material itself, which is also presented in online format. Students usually cannot pay great attention to the material in the text format. A today’s student spends from a few seconds to a few minutes on looking through and studying such material. Such approach is called “snack learning.”

Virtual education uses the concepts of “synchrony” and “asynchrony.” Traditional learning at a school lesson, a university seminar, or lecture is synchronous education. Thus, synchronous education is the education involving teachers and students in an interaction at the same time. We can add that teaching and learning here takes place in the same room, and the participants of the traditional teaching-learning process interact at the same time. Asynchronous education is the form of education independent on a place or time, and the interaction between its subjects can take place at different time. One of the examples of such education is a part-time education. Before, part-time students used to receive educational and methodological material by postage, to use audio and video records and broadcast.

In the modern virtual education, synchronous and asynchronous forms are changed. Synchrony in virtual education is teaching-learning in real time. Means of organizing such education are videoconferences, chats, webinars, and message exchange in real time. Here a tutor has an opportunity to respond to students’ activity, answer their questions, and influence their motivation. Asynchronous education has had a number of technology-driven stages in its development. With the introduction of ICT, asynchronous education has been advanced further. Nowadays on the basis of virtual education, asynchronous education in the form of essays, online tests, MOOC, SCORM, Wiki, etc. is successfully realized. Asynchronous realization of the educational process on the basis of the combination of Internet technology and multimedia courses provides an opportunity to project individual learning pathways, including “a convenient time and convenient place,” with the possibility of modifying learning material and technical solutions. Here,

the results of the activity itself, detection of reasons of achieving them, and the focus on the further optimization can serve as quality criteria. In the asynchronous education, a student is quite free; he/she does not have to sit behind a computer at a scheduled time and work with his/her classmates at the same time. In virtual education students are free to choose between synchronous and asynchronous teaching and learning methods.

Formats of Virtual Training: Definition and Effective Ways of their Use

Online Training as Democratization of Education

The most popular form of distance learning now is online training, or e-learning. Such training is conducted using multimedia and Internet technology.

In 1994 there appeared an interesting, in our view, article by Jeff Graham, Tom Alloway, and Lester Krames in the magazine "Behavior Research Methods, Instruments"; it is "Sniffy, the virtual rat: Simulated operant conditioning." The article shared experience in using the operant chamber for studying Sniffy rat. Diane Jass Ketelhut in *Journal of Science Education and Technology* (2007) spoke of the multiuser environment in the article "The Impact of Student Self-efficacy on Scientific Inquiry Skills: An Exploratory Investigation in River City, a Multi-user Virtual Environment." In the article "Spatial updating in superimposed real and virtual environments," Xiaolang Irene Wan et al. (2009) studied how people navigate in real and virtual environments. Training in the virtual environment and the experience of such training is quite widely presented within the medical community. Urresti-Gundlach et al. in *BMC Medical Education* (2017) presented the experience of their work in the article "Do virtual patients prepare medical students for the real world? Development and application of a framework to compare a virtual patient collection with population data."

The experience of using various forms of virtual training in a number of articles was summarized. Kerimbayev (2016) in his article noted that

it was important to consider two basic moments, i.e., impact mode of using virtual environment at training process within one faculty of the university, directly at training quality, and what outcomes can be reached therewith. The work significance consists in studying the virtual environment effect instead of traditional educational outlook and online training in pedagogical sphere. He considers virtual (digital) educational resources, their potential adaptation to trainee's personality and realization during academic process at the university. Virtual training at the university is a total of virtual educational resource. Information and educational interaction exists in the process of subjects and objects interrelation. An integration of information and pedagogical technologies takes place in the process of subjects and objects interrelation. Herein training is connected with such human activity spheres as intellectual, cultural, emotional, and social.

The pioneers of experimenting with modern Internet technology are traditional education institutions. There appear a lot of articles revealing different aspects of distance and virtual learning.

The article "Virtual dialogues and exchanges. The social and cognitive dimensions of interactions among students" (2013) by Analia Claudia Chiecher and Danilo Silvio Donolo focuses on the topic of interactions among peers in virtual environments. The analytical approach considers both the cognitive dimension and the social dimension (addressed more recently in the literature) of interactions.

The current state of virtual education and search for answers to the question "How to design the process of virtual education?" is considered in a number of articles: "Supporting the education and well-being of children who are looked-after: what is the role of the virtual school?" by Drew and Banerjee (2018); "Augmented reality as multimedia: the case for situated vocabulary learning" by Marc Ericson C. Santos, Takafumi Taketomi, Goshiro Yamamoto, and others (2016); "Developing a mathematical modeling course in a virtual learning environment" by Orey and Rosa (2018); "Increasing student engagement through virtual interactions: How?" by Christopoulos et al. (2018); and in others articles.

As illustrated by a number of studies and methods of teaching in schools and universities, online education for some indicators leaves behind the traditional attendance-based format. The basic argument for online education and one of its most important features is democratization of the learning process. Online learning makes it possible to remove most of the barriers: geographical, physical, and financial. Students are able to study in their comfort zone, at home, or on the way to work. Besides, they can choose a more convenient time, content, and pace of study. Online education is much cheaper than the classical one; it is even free. At the same time, there are increasing opportunities for higher education institutions, which can have access to those students who cannot attend lessons personally.

Online education using various formats of Virtual Reality provides different categories of persons with an opportunity to acquire new knowledge and skills: parents having small children, people with health problems, full-time employees who would like to change jobs, or those who could not get education at the time. Thus, such type of education as online education providing opportunities to study for different sectors of society and different categories of its persons is a factor of democratization of education.

The availability and openness of knowledge are accompanied by the development of digital technology. Online tools, the formats of Virtual Reality, which offer the largest possible number of people an opportunity to study subjects taught, are developed. Constantly increasing technical opportunities for communication, delivery, and consumption of online content led to the creation of first independent e-learning agents. They are both Moodle for discussions among students and RSS subscription for the dissemination of the material.

In the case of distance learning, students and teachers can be anywhere in the world. And using 3D glasses or helmets, all participants dive into the virtual world. Each of them can create an Avatar image, which can be present in a virtual classroom. Besides, students can listen to lectures and perform individual or group tasks.

On effectiveness, simulation can even exceed a real teaching process since things are speeding up here; the space is concentrated; and, in contrast to reality, it is focused on increasing the amount of the material taught. With a help of simulations, one immerses in learning experiences, in which processes, knowledge, and skills are highlighted clearly, which is impossible to achieve in reality.

Simulations are one of the most effective training formats, since they provide opportunities to experiment, study, and repeatedly use a new knowledge within a safe model. A high-quality simulation helps some trainees and groups of trainees to develop a high level of understanding and to realize how their conclusions and intuitive reactions influence on what happens to the personnel and the institution as a whole. But it is possible only when simulation looks as reality. The participants “coming out of” the simulation should feel truly that they themselves have been in it, not just their characters.

The infrastructure of distance learning consists of organizational and technical solutions on virtual communication. Among means of communication enabling to realize training online, the following common and most available ones can be identified:

- Mobile telephones.
- Discourse via social networks.
- Collaboration under LMS Moodle.

If a student cannot attend lessons for special reasons, we can give him/her an opportunity to do it remotely. For this aim a classroom is to be equipped by a special camera, which surveys in the format of 360° and transmits a panoramic video of the whole classroom. The students attending a lesson remotely will be able to watch what happens in the classroom in the first person (e.g., from their place), to see their classmates, to communicate with their teacher, and to participate in the lesson. Virtual Reality helps remove drawbacks, which can appear during videoconferences or distance lessons, creating the effect of the personal presence. The teacher can see when a student has to “go out of the

classroom” since helmets with built-in light sensors show whether the device is used by somebody or not.

Tools of Virtual Education

For trainees the immersion in the virtual environment is a kind of training in which not only face-to-face meetings are “created,” but which offers various tools for their joint activities.

Online education defines the character of the teaching and learning process, its educational options. Today most students use their smartphones when taking some courses. That is why mobile versions of courses and applications are becoming a necessary requirement.

Web Meetings

This tool includes audio podcasts, record keeping, handling of archives, a joint work with a desktop, software for painting and drawing, and chats as well. The *format of video lectures* is convenient in distance learning for gaining more knowledge on a profession or for developing professional skills. A video lecture is the video record of the lecture material including fragments demonstrating a subject under study. Students are able to look through the material at their convenience. *Webinars* are “virtual” seminars organized through IT; they represent a remote mode of training in the form of videoconferences and virtual lessons. This system enables to hold videoconferences, talks, interviews, and teaching in real time. Videoconferences represent training in groups; here students can interact with an instructor in the “question-answer” format and listen to a lecture material. Training is organized via special programs supporting multichannel communication (Skype). The webinar format is widely used in distance learning within interactive lectures and seminars. Such kind of training combines an opportunity to cover a big audience and interactive engagement of users and teachers.

Virtual Classrooms

Virtual classrooms enable to organize content libraries; thematic archives; testing on the material studied; surveys of students’ knowledge, abilities, and skills; and assessment tools.

Open online courses enable to study a certain discipline remotely or to improve professional skills. As supplements to traditional materials of a training course, such as video, reading, and homework, massive open online courses provide an opportunity to use users’ interactive forums.

Online courses enable students to gain required credit points while studying in universities – partners. Universities and colleges offer mixed or hybrid programs, in which standard “alive” lectures are combined with working online. Thus, one can attend lessons remotely, i.e., connecting to a translation in real time (synchronous operation) or listening to the recordings (asynchronous operation); a course can include Skype sessions and webinars.

Educational institutions are working at developing massive open online courses (MOOC). Today such courses on special MOOC platforms present the fastest developing sector of distance learning.

Virtual Learning Environment

Virtual learning environment is a standing environment on the browser platform. It provides an easy access to information, thematic experts, and colleagues in real time. Such tools are used for the integration of informal and formal education based on simultaneous use of video and audio podcasts, virtual classrooms, web-based resources, and social networks into common educational space.

Simulators are used in the virtual learning environment. The traditional approach to learning is expected to change to full gamification, flexibility and the use of the latest technologies for better and full understanding of the gained knowledge. One of such tools is Dialog Simulator format with elements of gamification.

An example is the “Maze,” an educational virtual game with the support of 3D glasses (Fig. 1). In the game one must find the exit from the maze and gather 12 keys. Performing required actions a player develops his attention, motor skills, and spatial orientation.

Along with Virtual Reality (VR), it is better to use augmented reality (AR). Augmented reality

Formats of Virtual Learning, Fig. 1 Fragment of the software for the virtual game, “Maze”

enriches existing technologies with unique ones and enlarges the horizons of virtual potential.

The Dialog Simulator format is the most effective for learning when one needs to develop practical skills. Dialog Simulator enables to immerse entirely in virtual learning. Dialog Simulator can represent an interactive game simulator with an intricate plot and articulated dialogs. It is perfect for training skills related to communication. It provides more interactivity, fuller involvement, and greater learning efficiency.

Dialog Simulator entirely “plunges” a trainee into history, and it is ideal for training managerial and communicative skills.

An educational game is effective if it is necessary to develop particular professional skills.

The use of interactive cases for teaching is the most effective way for developing required practical skills. Cases enable to train required skills within a safe gaming environment, to analyze mistakes made in the game, and avoid them in real-life situations.

Tests are used for controlling a user’s knowledge both in the process of learning and for

summarizing learning outcomes after studying a certain topic.

The creation of the virtual environment using methods of three-dimensional modeling enables a user to train the practical skills, which require a special training.

The basic objective of the online directory is creation of the single information and conceptual field for all users. Having a great number of users and having to accumulate knowledge base, it is useful to store it in a single place.

WIKI (encyclopedia) is a knowledge base, using which students work independently when they need certain information. The instructor works at granting students’ requests for information providing new articles to the knowledge base. The creation of one’s own knowledge base in the corporate network increases the attendance and the overall training level of employees.

Format of Students’ Direct Communication (Blog, Chat, Forums, Social Networks, Etc.)

Such communication can take place both among students of the same university and among

students from different universities. Such complex inter-institutional system of gaining knowledge works through using distance learning sites of the institutions, which have reciprocal hyperlinks.

The social networks such as “My world” (www.mail.ru), “In contact” (www.vkontakte.ru), which is very popular with youngsters, and “Facebook” (www.facebook.com) can be used as tools of distance learning technologies.

Chats, forums, and conferences in social networks are kinds of virtual communication. Students can organize chats and conferences and create contemporary groups for preparing for exams and discussing some content questions in real time. The participation of a teacher in such chats turns a “vertical” interaction to “horizontal” one; it causes greater confidence among students and contributes to improve the process of acquiring information.

As an example can use “Virtual,” the portal, which introduces a text chat, using which one can communicate during a virtual training course.

Chat supports a great number of simultaneously connected users due to the asynchronous architecture in real time. When one user writes a message, another one receives it immediately. In one chat “room,” several users can communicate simultaneously. During lessons students use chat for discussing the material taught, expressing their opinions and points of view concerning a problem. In order to enjoy a conversation, it certainly should be interesting. Having analyzed interlocutors’ messages, one can make conclusions how well they acquired the material taught.

Social networks help reduce the time spent on notifying trainees of coming events in the learning process. It becomes possible to counsel lesson bunkers and lesser students, since they can be reached more frequently in social networks than in classrooms. Communication can take place through comments in discussions and real-time messages among those participants who are online at the moment. Communication in social networks has a number of advantages; one of them is that students communicate in informal environment when a student can ask questions to a teacher without being afraid of looking unaware

of the answer to a question. Today youngsters spend a lot of time in social networks, and their communication along with the possibility to gain knowledge through social networks is becoming a familiar and pleasant experience for them, which results on more effective acquirement of learning material.

The use of a social network will be effective if a teacher places a link to a distance learning site on his/her (teacher’s) site as an additional learning resource.

Thus, thanks to using educational sites and social networks, students adapt easier when they study a new discipline, since they enter a specific information environment, which is created by their teacher, save time for searching for new information, and can get their home task at their convenience.

Virtual Laboratory Format

Virtual laboratory is the software-hardware complex enabling to experiment without reality. A virtual laboratory can be accessed via a computer, including the Internet. A virtual laboratory enables to replace real laboratory studies by math modeling of the processes under study with a virtual interaction of a student with laboratory facilities. The possibilities provided by modern imitational computer models create a perfect illusion of working with real equipment. A virtual laboratory makes it possible to observe periods of physical or chemical phenomena, which are impossible to see in real time, and to model processes, which are impossible in the real laboratory.

Thanks to the virtual laboratory, it is possible to examine processes in details and observe what is taking place in different time scale, which is relevant to the processes taking a fraction of a second or, on the contrary, lasting for several years. An important advantage of the use of virtual laboratories is safety when working, for example, with high voltage or with chemicals. Since a computer manages a virtual process, it is possible to quickly conduct a series of experiments with different values of input parameters, which is often necessary for correlating output parameters with input ones.

The disadvantage of a real laboratory is the problem of inputting gained information to the

computer. There is not such need in a virtual laboratory, since data can be saved in the electronic results table directly with experimenting by an experimenter or automatically. Therefore, time is saved and the number of possible mistakes decreases.

Virtual Reality Format in Mobile Learning

Today almost all people have mobile devices, mobile phones, or tablets, including even very young children. While children mostly use them for playing, adults use them as an “information navigator”: they read news, map routs, seek contact information, etc. The diversity of the consumed content has one similarity, its relevance. Taking a smartphone we search for the information, which we need here and now, which is exact and sufficient.

Mobile learning must also be relevant in this regard. Mobile devices enable to organize learning independently of the location and time. Most mobile devices have built-in sensors or special applications, which can, for instance, recognize a voice, have location services, and can measure the speed and direction of their owners and even their biorhythms.

We, for example, have developed a pulse sensor. It is a tiny programmable heart rate monitor, which triggers the alarm at the doctor’s phone when the patient’s heart rate is slow (Fig. 2).

Data of mobile analytics of using educational systems, sites, and applications, combined with a

user’s physiological, geolocation-based and other personal data, offer great prospects for creating a personalized system of e-learning. Today new technologies combine the potentials of networks, smartphones, messengers, and online maps.

The implementation of mobile learning has been possible by a broad set of functions of modern mobile devices, which today include voice communications, messaging, graph sharing, Internet browsers, and others.

There are increasing opportunities of social networks in the sphere of Virtual Reality. An interactive telephone conference can be held among several friends. Users can “meet” in 3D virtual world connecting headphones to their telephones.

The system of mobile learning in Virtual Reality solves such urgent problem as realization of a high degree of trainees’ socialization, development of their communicative competences, and the ability to work as a team.

Mobile learning with the use of Virtual Reality requires the development of mobile applications. Such mobile applications should have certain functions enabling to perform various actions.

Referring to mobile applications for education, it is worth mentioning their possibility of accessing cloud services, which are used as a single information field for storing the information of students and teachers and indicators of learning and teaching activities.

Cloud Format

Cloud is a model of online repository, in which data is stored and processed in virtual server. Physically such servers can be located geographically remotely one from another. Besides, this format enables to hold a so-called cloud videoconference. Connection via videoconference requires relevant equipment, software, and a team of experts. But the emergence of the “cloud-related solution” allows avoiding these requirements.

During a cloud videoconference, users are physically present anywhere in the world; the main thing is access to the Internet. Besides, thousands of users can participate in the same videoconference simultaneously. It is quite easy: an

Formats of Virtual Learning, Fig. 2 Hardware implementation of the heart rate monitor, “pulse sensor”

initiator inputs the title and the time of a conference, sends invitation to users via e-mail, clicks at the link in the browser, and becomes the conference participant.

The study undertaken in this area suggests that students consider virtual learning efficient and even more qualified than the traditional education.

Virtual Reality (VR) Promising Formats and Disadvantages of Introducing VR into Education

Virtual worlds are the most complicated and the most promising tools for organizing training. Their use requires very sophisticated software. Such training faces increased requirements for a teaching staff and service personnel. It enables to introduce the most complicated scenarios of informal and formal education. Virtual worlds are the most cost-effective and efficient solutions for organizing distance learning. Virtual learning environment is being implemented in institutions owing to its economy, interactivity, and simplicity of use. It is much more difficult for adult students to adapt to the real learning process. They feel much more confident in a virtual environment. This explains sympathy for virtual environments; besides they focus on the thematic content and are constantly developing technologically.

What opportunities for education does Virtual Reality propose? Today education is considered one of the most promising areas for developing and introducing Virtual Reality technology. The idea of applying Virtual Reality to teaching and learning is not new anymore, and VR technology has been used for a long time, from virtual excursions at History or Geography lessons to training flying a plane or running a bullet train. Virtual Reality provides new opportunities for studying theory and improving practice, since traditional methods can be rather costly or too complicated.

There are five basic advantages of using VR in the education sector.

- **Visibility.** 3D graphics enables to reproduce the detail of even most complex processes invisible to the human eye, up to the decomposition of nucleus or chemical reactions.

Besides, nothing prevents from improving the level of detail in order to see the movement of electrons or to reproduce, for instance, a mechanical model of the development of a human body's cell at different stages. Virtual Reality enables to reproduce or model any processes or phenomena known to contemporary science.

- **Safety.** Practical fundamentals of piloting aircrafts and jet planes can be perfectly safely mastered at a VR device. Besides, VR enables to train too complicated medical operations or manipulations without harming the humans or putting them at risk.
- **Involvement.** VR technologies enable to model any mechanics of activities or behavior of an object, to solve complicated mathematical problems in the form of games, etc. Virtual Reality enables to travel in time looking through main scenarios of important historical events or to see the inside of humans at the level of the movement of red blood cells.
- **Focusing.** A space modeled in VR can be easily examined in 360° panoramic view not distracted by external factors.
- **Possibility of conducting virtual lectures.** Thanks to the option for displaying a modeled first-person space and the effect of one's own participation in virtual events, it has made possible to conduct different types of lessons in Virtual Reality mode.

Let us consider what advantages and disadvantages learning in Virtual Reality mode has.

Formats of VR in education trigger the process of gaining required material. Besides being able to read or listen of the most extraordinary experiments, trainees can see them before their eyes. Virtual Reality technology provides excellent opportunities for acquiring an empirical material. The traditional lesson format remains almost unchanged; it is only supplemented by the immersion into VR for 5–10 min. It is possible to divide one lesson into several stages, in each of which the most complicated moments are visualized in the virtual world. As before the basis of the presentation of a new material remains a lecture. But

Virtual Reality enables to improve a lesson by involving students in full immersion in learning process visualizing key moments of the material covered. When learning in Virtual Reality mode, the efficiency, the level of memorizing information, and the interest in learning increase. VR technology offers opportunities to model any situations, including emergency, which are difficult or impossible to realize when learning in real life; there is no necessity to take any risk of being injured, as, e.g., through handling high-risk equipment; there is no necessity for a trainee to be present at hazardous establishments; there is no risk of damaging real equipment when learning; VR simulators are cheaper than complex and cumbersome life-size training devices, which have to be bought and installed.

At the present stage, the newest models of VR devices have not yet been developed perfectly for their full application in order to teach at school or university; therefore, the potential use of Virtual Reality has a number of disadvantages.

- Workload and labor intensity. Almost every subject has a large amount of an important material; therefore, the creation of one such course requires a lot of work for creating a virtual content. It can be both a specific lesson on each topic and dozens of specific applications. The companies, which plan to work on developing lessons in Virtual Reality mode, have to be prepared to the fact that this process will take a lot of time and resources without the possibility to make a profit until a proper lesson or a complete course consisting of several lessons is developed.
- Cost of equipment. In the case of distance learning, students need to be concerned about accessing gadgets able to visualize Virtual Reality; besides, educational institutions need to purchase an expensive equipment for the classrooms, where virtual lessons are conducted, which requires a lot of money.
- Functionality. Like any other similar technology, Virtual Reality needs to use its own language. In order to create a perfect virtual lesson, one needs to choose proper tools.

- Existing applications of Virtual Reality for education cannot take advantage of all potential of the technology and, therefore, do not perform their core functions.

Virtual Reality technology can be applied to education, and most likely in the near future, we will be able to witness a real breakthrough in this area and numerous interesting discoveries.

Conclusion

Prospects for the development of virtual learning are that in the future, such type of education will become usual and content-oriented. As an integral component of the universal social educational structure, this type of tutoring will become more useful and widespread. It will affect virtual education of the future. It will become even more available and informative and enable more people to participate in the process of gaining knowledge. However, it will not be able to completely displace more common for us form of learning. Technologies of virtual communication will be approaching to modeling its real analogue with time.

[Edutainment](#)

Definition

Digital game-based learning (DGBL) is increasingly being used to refer to the use of games for expected learning outcomes. The expression emphasizes the importance of the context of using digital games for educational purpose rather than the use of stand-alone applications (Egenfeldt-Nielsen et al. [2011](#)). Game-based learning (GBL) usually refers to the use of digital games called serious games, digital learning, or educational games. However, non-digital games are also widely used for educational purposes. GBL is not often clearly defined in research papers. This is probably due to the difficulty to defining what playing means. Two main criteria emerge (Brougère [2000](#)). The first criteria is the second-degree, the meta-level of the activity. A same conduct might be considered to be a game or not depending on the meaning of the activity. As a consequence, a game is frivolous and nonproductive. The second criteria consist of the

autonomy of the player. He/she is allowed to take his/her own decisions and to shape his/her decision. This autonomy is framed by rules and uncertainty always remains in regard to the ending. A core characteristic of a game is its agonistic dimension. A game is an artificial conflict (Salen and Zimmerman [2004](#)) where a player competes with the game itself or opponents.

DGBL is a complex educational practice. It includes a large variety of games and gameplays, subjects and disciplines, formal and non-formal educational contexts, school levels, and also a variety of teaching, training, or other educational practices. In addition, DGBL does not only refer to the use of a specific game for expected learning outcomes. DGBL also refers to a learning scenario where playing is important, but is not limited to the use of a game. In particular, DGBL includes debriefing that is recognized important for the metacognition and the transfer of knowledge.

DGBL is close to gamification of learning contexts. However, while gamification refers to the implementation of motivational affordances in non-gaming educational contexts, DGBL refers to the use of a specific game, called serious games, educational game, or learning game for expected learning outcomes.

Introduction

The usage of games for educational purposes is not a new idea. Already, in the Greco-Roman

world, Plato, Aristo, and Quintilius valued the contribution of play to the moral and physical child's development. In Greek, *paidia* (play) and *paideia* (education) have the same roots. In Latin *ludus* means both game and school. The idea that playing might have an educational value came back during the humanist area after a long period in which playing has been mostly rejected. Later on, in Europe, Fröbel (1782–1852), a German pedagogue, played an important role in spreading the idea that play might have an educational value. However, game-based learning has been mainly restricted to nursery school for a long time. Play is recognized to be important for child development (Piaget 1945); however, this idea has been challenged by Sutton-Smith in a book published in 1997, *The Ambiguity of Play*. Sutton-Smith underlines that there is rhetoric of play as progress, which poses play as a developmental arena, not supported by evidences but by values and ideologies.

The development of digital technologies that enable game design in various fields offers new opportunities for teaching and learning and digital video games were already employed in the 1970s (Egenfeldt-Nielsen et al. 2011). Today, digital game-based learning (DGBL) attracts more and more attention from educators and educational researchers. Learning games are now used in primary and secondary schools and also for vocational education. DGBL is used at university and by companies for training professionals. Persuasive games are also used by activists, politicians, and institutions. As a result, more and more research projects try to assess the educational value of learning games or to understand how playing is connected to learning.

DGBL is grounded on different educational theories. In a meta-analysis, Wu et al. (2012) distinguish DBGL based on behaviorism. Learning is considered to be produced by stimulation and reinforcement due to the feedbacks provided by the game. For cognitivists, DGBL is based on the acquisition of knowledge and growth of the mental structure: information is received, processed, and organized into existing schema. Humanists stress the importance of construction of meaning for learning. They emphasize that DGBL is student centered and personalized and

foster student's motivation. Constructivism and social constructivism consider learning to be an active, constructive, and social process. DGBL is grounded on its situated and experiential feature.

From this complex landscape of GBL, two main approaches emerge. The first approach valuing DGBL is in line with Prensky claims (Prensky 2001) and the concept of edutainment, a form of entertainment designed to be educational. DGBL has its roots in the humanist tradition expressed in *De civilitate morum puerilium*, a handbook written by Erasme (1467–1536). Thus, DGBL is considered to address some of the pitfalls faced by educators such as lack of student's motivation or student's confidence (Egenfeldt-Nielsen et al. 2011). The second one is based on the idea that games might have an intrinsic educational value. This perspective is more in line with Fröbel's ideas (Brougère 2000) and constructivist and cognitivist theories. According to this approach, the educational value of a learning game is not limited to its power to motivate students but results from the contextualization of knowledge in a challenging situation where the player can assess his/her way of thinking and behaving and develop the needed knowledge to adjust to this situation (Sanchez 2017).

An overview of the main principle of educational theories supporting DGBL is proposed in section “[Toward a Game-Based Learning Theory](#).” In section “[Diversity of Games and Gameplays for Learning](#),” we briefly describe the diversity of learning games and, in section “[Different Uses of Games for Educational Purposes](#),” the diversity of the contexts for their use. Section “[Challenges and Criticisms Leveled](#)” is dedicated to emphasize the challenges faced for the implementation of DGBL and Section “[Current Trends in Research](#)” to current trends in DGBL research.

Toward a Game-Based Learning Theory

Game-Based Learning as Experiential Learning

Game-based learning has close relationships with problem-solving. Indeed, a game is an “artificial conflict” (Salen and Zimmerman 2004), a challenge that must be resolved by the learner. The

learner/player faces an antagonist system composed by the game itself or adversaries (Sanchez 2017). The objectives of the player are antagonized by the resistance of the system, and the game becomes a factor of difficulties and disequilibrium (Balacheff et al. 1997). A conflict arises, and the player/learner takes decisions and shapes strategies based on his/her conception (even misconceptions), and bad decisions are punished with loss of points. Hence, from the player perspective, it demands to shape strategies and to develop the knowledge needed to win (Ibid.). This view of DGBL is line with Piagetian theories. Learning results from the adaptation of the learner to the game and, as a result, from the interactions that emerge within a given situation. Thus, learning from games has close relationships with learning from simulations and microworlds (Papert 1980). DGBL has also been linked with situated learning (Lave and Wenger 1991). For example, the so-called epistemic games (Sanchez et al. 2013; Shaffer 2006) offer the player/learner the opportunity to acting and learning professional practices. The player/learner is supposed to make his/her own discoveries and to learn from trial and error strategies through self-regulated learning. By recognizing inappropriate knowledge, the player/learner revises his/her knowledge and learns from his/her reflection on playing.

As a result, the core concepts of DGBL are interactions and feedbacks. Meaningful feedbacks provided with rewards (points, bonuses, or badges) play the role of a formative assessment. In addition, errors become useful for the learning process and provoke minimized consequences if compared with traditional teaching. These *graceful failures* (Plass et al. 2015) encourage risk-taking and further explorations. In this perspective, game-based learning is grounded on the philosophy of John Dewey and the idea of experiential learning (Dewey 1938).

Games-Based Learning as a Social Practice

Games have also been considered as demarcated universes or *magic circles* (Huizinga 1955) that stimulate a form of social practice. Social practices can take the form of collaboration so that teammates are involved in epistemic interactions (Ohlsson 1995) and learning consists in social

participation (Wenger 1998). Epistemic interaction can involve different interactive processes such as explanation, production of an articulated discourse, elaboration of meaning, or clarification of views (Baker 1999). Teammates extend and make explicit the knowledge needed to address the challenge (ter Vrugte et al. 2015). By doing that, knowledge is developed, discussed, assessed, and shared. However, some authors stress that the positive effect on learning also depends on the epistemic quality of dialogues (Van der Meij et al. 2011).

Avatars have also been recognized to be important for DGBL. When players are represented by an avatar, the avatar plays the role of a projective identity (Gee 2003) in two different meanings. First, avatar is an Indian word which means incarnation. It allows the players to have a self-experience through introjection. The avatar plays the role of a mirror reflecting on his/her own values and choices. For example, he/she is led to check the relevance of the decisions he/she make by getting or losing points. The player immerses into a role, and he/she is protected from the consequences of his/her errors and failures that are assumed by his avatar. Second, the avatar is an emblematic figure which becomes the projection of an identity, an ideal figure in which the player can project his ideas, values, and desires and, therefore, find the opportunity of self-development (Sanchez et al. 2016b).

Context and Teacher's Roles

Numerous meta-analyses are inconclusive regarding the positive or negative effects of DGBL as individual cases could differ widely. Game, as a generic term, is so broad, that it is difficult to compare case studies. In addition, the studies differ in terms of types of games, subjects, integration into learning scenarios, school levels, and contexts for their use.

Depending on school systems, cultural traditions, and educational policies, DGBL might be favored or disfavored. In Europe, different initiatives have been taken for the promotion of DGBL. For example, in 2008, the European Commission launched a program for the development of the use of digital games in school (Pivec and Pivec 2008).

The teacher's role has been recognized as a key factor for a successful implementation of DGBL. Teachers might participate to the game design (Sanchez et al. 2017). They are concerned with the selection of games adapted to their teaching objectives and the design of relevant scenarios. They might play the role of game-masters and use Play Management System designed to support both players and teachers to deliver, use, manage, and track play situations (Sanchez et al. 2016a).

There is a difference between mastering the rules of the game and recognizing the ways those rules structure our perception of reality (Jenkins et al. 2006). Thus, it is important that players/learners become able to evaluate the distance between the game and reality. In addition, learning occurs only after reflection and debriefing (Garris et al. 2002). Debriefing plays different roles for DGBL. First, debriefing fosters reflection and metacognition. The implicit knowledge dedicated to play becomes explicit through an after-playing debating session. Brousseau (Balacheff et al. 1997) terms institutionalization this debriefing session. The word institutionalization stresses that it leads to the change of the status of knowledge. The situated knowledge needed to win the game becomes more universal and is validated by an official external source, the teacher/trainer. Second, debriefing is recognized to be crucial for the transfer of knowledge and the learning experience is undermined if the players are not aware of the learning elements (Egenfeldt-Nielsen 2006). For some authors, the game-learned experience is transferable if the teacher clarifies the purpose of the simulation before using it (Aldrich 2005). However, the concern with debriefing seems to have been lost in a majority of research studies (Crookall 2010).

Diversity of Games and Gameplays for Learning

DGBL consists of the use of a huge diversity of games. All disciplines are concerned; however, business, mathematics, and science seem to be the most common disciplinary subjects addressed.

Some games that were not primarily designed for educational purposes have been adopted by teachers. For example, Civilization (MicroProse), a strategy game in which the player attempts to build an empire, is used to teach history (<https://civilization.com>). SimCity (Maxis), a game in which the challenge consists of founding and developing a city, is used by geography and economy teachers (<http://www.simcity.com>). Some physics teachers also designed learning scenarios for secondary students based on ballistic and mechanics studies with Angry Birds (Rovio Mobile), a game which consists of launching birds with the goal of destroying pigs. Many commercial games adapted to different disciplines have been adopted by teachers. For some of them, there is a specific version dedicated to education (<https://www.angrybirds.com>). SimCity EDU and Microsoft Educational Version of Minecraft launched in 2016 are the most famous of them. In 2017 Ubisoft announced a new version of the game Assassin's Creed Origins tailored for teaching ancient Egypt at school (<https://assassinscreed.ubisoft.com>).

Games primarily designed for learning and training are often referred as educational serious games, educational games, or learning games. They often take the form of video games for computers, iPad, or smartphones. For example, DragonBox is a famous series of educational math apps that are designed to teach algebra to primary students (<http://dragonbox.com>). Mechanica, (Creo) a game about physics for secondary students, and Tamagocours (Sanchez 2017), a game about copyright of educational resources for preservice teachers, have been designed by teams composed of educators, game designers, and researchers (<http://www.mecanika.ca>).

Numerous serious games have also been designed for training professionals such as soldiers (e.g., America's Army (<https://www.americasarmy.com>)) or surgeons (e.g., Touch Surgery (<https://www.touchsurgery.com>)), and the training sector has put considerable effort and money to improve professional training with DGBL. The health sector has also adopted DGBL for professional and patients.

There is also a huge diversity of games in terms of game apparatus and gameplays. The most common games are video games, online video games, or apps for cellphones and tablets. DGBL also encompasses location-based games, role-play games. Since several years, new games attract more and more attention. Alternate reality games enable for the design of complex learning environment that combines physical reality and simulations. During the recent years, teachers have also designed escape games with educational content. S'CAPE, an online platform, enables teachers to share their games and to collaborate for designing the games (<http://scape.enepe.fr>).

Different Uses of Games for Educational Purposes

Fostering Motivation and Engagement

Following a humanist tradition, DGBL is often considered to have the power to promote positive attitudes toward disciplines (Ke 2008), to make the learning experience more enjoyable, to foster student's motivation, and to engage students to learn (Dickey 2005; Jabbar and Felicia 2015). The main reasons that are evoked are grounded in the self-determination theory (Ryan and Deci 2000). Games are known to fulfill innate human psychological needs such as autonomy (freedom framed by rules), self-confidence (game levels that promote successes), and relatedness (interactions with teammates and adversaries). Flow is also often mentioned. Flow is defined as the highest degree of motivation by being completely involved in an activity for its own sake (Csikszentmihalyi 1990). However, engagement in games is not only related to elements inherent in games. It depends, as well, to the attributes of players such as motivation to play, playing styles, ages, or gender (Connolly et al. 2012).

Drill and Practice: Games for Training

Like simulations, games offer the opportunity to practice in a safe environment. The learner can test different strategies and make mistake without bad consequences. Moreover, bad strategies can be experimented and their outcomes assessed.

Thus, DGBL have been used to train professionals for the development of various competences. One of the most famous examples relates to America's Army which is used for the recruitment and training of soldiers. Serious games are also used to train pilots to handle unknown and unexpected situations (Kuindersma et al. 2017) and teachers to react to school mass shooting (EDGE – Enhanced Dynamic Geo-Social Environment (<https://www.dhs.gov>)).

Different games have also been designed to train professional to interact with customers (*Adoptez la client attitude* !(<http://www.ktm-advance.com>)) or employees (*Entretien Annuel d'Evaluation*¹¹).

Raising Awareness with Persuasive Games

Serious games also realize a new form of rhetoric (Bogost 2007). Thus, some of them have been designed to persuade people to adopt a specific conduct or to change their opinion. They are called persuasive games. For example, there is a huge diversity of games for health that intend to help people to adopt conduct for preventing or treating disease and to develop self-management skills. There are many examples of such games for young diabetics (Times Out) or obese persons (Fat World (<http://www.gamesforchange.org/play/fatworld/>)).

Numerous games are also employed to raise people awareness on social and environmental issues such as fight against terrorism (September 12th (<http://www.gamesforchange.org>)), consequences of the exploitation of oil shale (Fort Mac Money (<http://www.fortmcmoney.com>)), or fast food (McDonalds (<http://molleindustria.org/>)).

All the examples mentioned above elaborate on the idea that a game is a medium that can support or disrupt conducts or social positions through procedural rhetoric, i.e., rule-based representations and interactions (Bogost 2007).

Learning from Creating Games and Modding

In a study published in 2011, Vos et al. (2011) concluded that students involved in creating games demonstrated more cognitive competence than those who just played existing games. Some platforms enables for the creation of games. For

example, Scratch (Resnick et al. 2009) enables young learners to develop computational thinking through the creation of mini games. DGBL can also take the form of modding. Modding consists of the alteration of already existing games. Bayliss (2012) reports on modding the commercial game Minecraft for a course on artificial intelligence.

Assessing Skills with Games

In general, games provide immediate feedbacks to the actions performed by the player/learner. As a result, a game plays the role of a space for reflexivity within which the player can test his ways of behaving because his/her decisions translate into immediate feedback (Sanchez et al. 2016b). Gee and Shaffer (2010) develop a similar idea when they state that we are wrong when we design games for learning; they should be designed for testing, and they are assessment systems (Shaffer 2007). The same authors stress that inherently require and assess a set of twenty-first-century skills. Indeed, the so-called epistemic games (Shaffer 2006) enable for distinguishing between experts and novices than can any standard paper-and-pencil test.

Such an approach has been followed by Renault Trucks, a French company. The company developed a game dedicated to train their employees to interact with customers. Finally, they recognized that the game did not add any value to the training. However the company decided to use the game as an assessment system as it demonstrated its power to assess the skills required to interact with customers.

Information and Media Literacy

Since digital games represent now an economic sector with a more important turnover than the trade of books or music, there is a need to develop game literacy for the young generation (Buckingham and Burn 2007). As a result, games should not be regarded merely as educational tools. Education about games should be taken into account. Indeed, the gaming culture is important for the new generation. In addition, playing a game can become a persuasion to believe in the general ideology surrounding them (Sutton-Smith 1997). Thus, game literacy is a form of media literacy. This issue has been addressed by

teachers. A blog post reports how Pascal Mériaux, a French history teacher, has integrated Assassin's Creed into his course on the French revolution (<https://blogs.microsoft.fr/enseigner-lhistoire-geo-avec-assassins-creed-cest-lidee-geniale-de-ce-professeur-de-lycee/>). Students are asked to discuss the representation of this period by the game.

Challenges and Criticisms Levelled

Digital game-based learning has often faced criticisms and has been called chocolate-covered broccoli approach (Bruckman 1999) or sugar-coating education (Kirriemuir and McFarlane 2004). Disguised educational content is recognized to have a negative effect. These criticisms are in line with Freinet's opinion. Freinet draws a distinction between play-work and work-play. Play-work is free play which can become bad kind of play. Work-play, on the other hand, is real and productive work done by children (Freinet 1946). There is also a non-negligible proportion of students that is reluctant to consider that learning result from playing (Egenfeldt-Nielsen 2007) or who prefer direct instruction. Another criticism levelled is the short-term effect of DGBL. When the novelty of using reward system within games wore off, the learners' engagement decreased (Ronimus et al. 2014).

Thus, the difficult challenge faced by game designers consists of merging gameplay and educational content. The so-called serious games are often designed by educators and not by game designers. They are often poor in terms of playfulness. Others game might be fun but not really educational since the players can address the challenge with no learning gain. Game mechanics should be aligned with the learning goals of the game. Games that manage to combine attractive gameplay and educational content are said to be intrinsic (Habgood 2007).

Current Trends in Research

A majority of current research falls within an essentialist viewpoint on DGBL. The functions of a game are considered resulting from a set of

attributes that might be studied independently. For example, some studies focus on the effect of specific game mechanics like competition (ter Vrugte et al. 2015) or game elements (Filsecker and Hickey 2014). A new research trend is currently emerging. Play is considered to be performative (Sanchez and Mandran 2017) and to depend on the *lusory attitude* of an individual who accepts the arbitrary and artificial rules of the game. This emphasizing of the player is also noticeable in the expression *playful learning* proposed by Plass et al. (2015). Playful learning describes learning that incorporates game elements, even though the learning environment might not be considered a game. Already, in 2007 Mitgutsch advocated for the adoption of the expression play-based learning and thus emphasized the importance of the player. Henriot's work (Henriot 1969, 1989) about game and play is important regarding this question.

Playing analytics, the collection, and analysis of player's interactions with the game during play activity offer new opportunities for the understanding of DGBL. Most of the recent studies are limited to qualitative studies about numbers of players connected, players' clicks on the interface, or needed time for achievement. However, some researchers try to go beyond with players' strategies or error analysis (Sanchez and Mandran 2017). Playing analytics should play an important role for future research into DGBL.

Introduction

This entry presents an overview of how and why Learning Games are used in higher education.

Learning Games can be defined as games that are designed to captivate the learners' attention and facilitate their learning process. They have explicit educational purposes and can be used for teaching at all levels of education. All types of games can be used for learning: board games, card games, role-playing games, first-person shooter games, simulation games, management games, puzzle games, treasure hunts, etc.

The main characteristic of **Learning Games for higher education** is the fact that they are designed to teach specific complex skills taught at university or during professional training programs. Unfortunately, it is not infrequent to observe strong opposition on the part of this target audience to this mode of learning that these adult students associate with children.

The use of Learning Games in primary school seems natural to teachers and is encouraged by specialists in didactics and neuroscience. This learning technique is much less frequently used in middle school and is almost completely absent

from higher education. Yet teachers at all these levels are faced with the same problems, such as lack of motivation and investment, for which games are known to be an effective solution. This entry presents an overview of the games that can be used for higher education and the reasons why some teachers and students still show resistance to this type of learning. The numerous advantages of games for higher education will then be presented, citing games presently used in universities, in graduate schools, and for professional training. Finally, this entry presents the current research questions that need to be addressed concerning the design of games for higher education and the acceptance of these games by teachers.

Accepting Games in Higher Education

Teaching with Games

As children, we naturally use games as a pedagogical tool to enhance our emotional, sensory, motor, cognitive, intellectual, and social development. This natural process is adopted by teachers in primary schools to teach mathematics, history, art, music, and foreign languages (Kamii and DeVries 1980). This pedagogical approach aims to use game mechanics in order to captivate students' attention and engage them in their own learning process (Dondlinger 2007). When playing, **the learners become the central actors of their learning process**, a role quite unlike the passive position they occupy, most of the time, in traditional education. In order to win the Learning Game, students need to make decisions based on their newly acquired knowledge. Moreover, the **learners find themselves emotionally engaged** in the game, and this facilitates the memorization of their decisions (National Research Council 2000). Games can therefore be used to facilitate learning certain skills, for which traditional teaching methods are not satisfactory (Mayo 2007).

What Games for Teaching?

These past years, many digital Learning Games have been developed. **Digital Learning Games** do not require any physical material and offer

many advantages such as adapting to the learner's profile, allowing access to the game anytime and anywhere, and displaying infinite patience when it comes to repeating concepts. In addition, the new generation of students is accustomed to playing computer games. An American study carried out in 2000 showed that, on average, students who have obtained an undergraduate degree spent only 5000 h reading compared to 10,000 h playing video games and 20,000 h watching television (Prensky 2001). With the democratization of smartphones and tablets over the last 20 years, this tendency has no doubt been amplified. In 2015, 75% of Americans between 13 and 17 had access to smartphones, and more than half had access to tablets (Lenhart 2015). In this context, it is in our interest to provide tools and methods to help teachers use the attractiveness of video games to facilitate the acquisition of complex skills.

In order to be effective, Learning Games need to offer engaging game mechanics that serve the educational objectives. There are many theories on the best way to choose and integrate these game mechanics with the learning content. The **extrinsic motivation approach**, for example, was very common during the 1980s and 1990s, when Learning Games were referred to as "edutainment." With this approach, inspired by the behaviorist learning theories, gaming and learning are treated as separate entities. Indeed, the learners are usually first asked to perform certain educational exercises, and, if they succeed, they are given access to a short game or receive points and badges as a reward. This approach met much criticism and was often regarded as "sugar coating" over drill and practice exercises (Bruckman 1999). Nevertheless, this approach has become quite popular in higher education these last years under the term "gamification." Indeed, it is easy to gamify existing courses on online platforms used by universities and MOOCs (massive open online courses) (Gené et al. 2014). Many of these platforms offer plugins to create badges, progress bars, and leaderboards, and they show fun content only if the learners have achieved a certain goal (a certain number of points or activities, etc.). In regard to the limitations of this approach, several Learning Game designers

have chosen to explore another direction called **intrinsic motivation approach** (Fabricatore 2000; Kafai et al. 1998), influenced by the constructivist learning theories. It consists in blending game mechanics with the learning content instead of using them separately. The idea is to choose a game design that is adapted to the educational goal and weave it into the pedagogical activities. According to numerous studies (Habgood 2007; Lepper and Malone 1987; Ryan and Deci 2000), it is this cohesion between learning and fun that truly engages the students in their activity and facilitates the learning process. However, this approach implies creating custom Learning Games in collaboration with teachers and game designers, a very costly process that is not always possible. By combining both approaches, maximum efficiency can be obtained.

It is important to understand that the effectiveness of a Learning Game depends not only on the characteristics of the Learning Game artifact but also on the way it is used (Sanchez et al. 2017). Therefore, the game mechanics and the educational content do not necessarily need to be embedded in the Learning Game artifact itself. For example, teachers can use basic exercises in a fun context by distributing rewards, setting up battles between groups, or introducing the concept with a story. The other extreme is also possible, using a pure game, such as *Assassin's Creed* (Assassin's Creed Ubisoft, <https://assassinscreed.ubisoft.com/>), for educational purposes (teaching history (<https://www.youtube.com/watch?v=TAeut18BHOA>)).

Resistance to Learning Games

The use of Learning Games in the context of higher education is subject to many forms of resistance. First of all, the use of games with adult or young adults can be problematic because they often view games as futile and only fit for children (Eyster 2008). This opinion is sometimes shared by colleagues and superiors. Teachers who use Learning Games therefore need to prepare a flawless argumentation that shows how their Learning Games will help students reach the given educational goals.

Another critical concern is the student's evaluation: is it fair to evaluate learners according to

their scores and actions in the Learning Game? The nature of games, as defined by Caillois (1961), implies that playing can only be done free willingly and the actions taken in the game should not have any consequences on the real world. Using a Learning Game to grade students therefore contradicts the very notion of play.

Finally, it is unrealistic to believe that one Learning Game will suit all students. We all have different player profiles (Seeker, Survivor, Daredevil, Mastermind, Conqueror, Socializer, and Achiever) (BrainHex questionnaire, <http://survey.ihobo.com/BrainHex/>) and therefore do not necessarily like the same types of games (Nacke et al. 2014). This must be kept in mind when designing Learning Games: it is best to choose game mechanics that cover several player profiles.

Even though the use of Learning Games faces resistance in higher education and requires complex multidisciplinary design skills, many have proven their efficiency in various domains. In the next section, the advantages that games can offer for higher education will be presented and illustrated with examples of games presently used

in universities, graduate schools, and professional training programs.

Advantages of Games for Higher Education

An Opportunity to Simulate and Manipulate

Computer games have the advantage of offering adaptable virtual environments that are very useful for recreating specific situations and simulating the context in which learners will use their skills. This is particularly advantageous when the context is impossible or very difficult to reproduce because of its costly or dangerous nature. For example, *The Resuscitation Game* (The Resuscitation Game (imaginary), <https://www.youtube.com/watch?v=0aDzjJTWUsc&feature=youtu.be>) is used to teach medical procedures and reanimation technics for neonatal resuscitation. *Rail Simulator* (Rail Simulator (electronic Arts), <https://www.origin.com/fra/en-us/store/rail-simulator/rail-simulator>) (Fig. 1) allows future train drivers to validate their management and driving skills. Virtual reality is one of the latest advances in simulations. This

G

Games in Higher Education, Fig. 1 Train simulator (*Electronic Arts*) used for training train drivers. (Source: <https://www.origin.com>)

technology immerses the learners in an interactive virtual world and allows them to practice their orientation and manipulation skills. Virtual reality is also used for simulating stressful situations in order to help learners control their emotions (Marfisi-Schottman et al. 2018; Ponder et al. 2003).

Enhanced Emotional Engagement

Learning Games have the power of involving students in their own learning process with game mechanics such as competition, rewards, social recognition – and many more – that enhance motivation and activate the students' capacities (Dondlinger 2007). Learning Games offer much more than a simple simulation environment. They offer the possibility of creating role-playing games based on complex scenarios with stories and quests. Thanks to these mechanics, learners can project themselves into a character and are emotionally engaged in the action of helping this character attain his/her goal. Throughout the game, the character will need to master various

skills to fulfill his/her objectives. Many educational games offer such engaging scenarios. *Starbank The Game* (<http://serious.gameclassification.com/EN/games/14090-Starbank/index.html>) (Fig. 2), for example, is used to train new bank employees; *Les aventures de Casey Warren* (<http://blog.seriousgame.be/les-aventures-de-casey-warren>) is used to train employees in data security.

Relief from Routine

Using games is a good way to break the routine that sets in after several months of class. Introducing this teaching method changes the usual dynamics of the class and gives a second chance to the students who feel they are too far behind or that have given up all interest in the class. The games also require a set of new skills (communication, organization, tactical planning) that are not usually put forward in class. This provides teachers with fresh insights into their students as learners (Kirriemuir and Mcfarlane 2004). Games also create a break, a state of “relaxed attention” that

Games in Higher Education, Fig. 2 Starbank The Game (BNP Paribas), used to train bank employees. (Source: <http://serious.gameclassification.com>)

Games in Higher Education, Fig. 3 CheckiO used for teaching computer programming. (Source: <https://checkio.org/>)

enhances learning (Thiagarajan and Thiagarajan 2003). *CheckiO* (<https://checkio.org/>) (Fig. 3), for example, offers a new approach for learning Python and JavaScript programming languages.

A New Student-Teacher Relationship

Games can also be designed to help teachers. It is possible to integrate certain repetitive tasks into the games such as the explanation of certain concepts or corrections. This gives the teacher more time to interact with the students, to advise them, and to help those in need. The student-teacher relationship is therefore redefined.

In addition, when it comes to training adults, who already have professional experience, games can turn out to be better suited than traditional training (Federation of American Scientist 2006; Mayo 2007). This can be explained by the fact that adults find it difficult to “go back to school” and accept criticism from a teacher, who is often younger than them. Learning Games offer an original, less academic way of learning. In addition, the

games can be designed so that all forms of judgment come from the game and not the teacher. In *Laboratorium of Epidemiology* (<http://loe.ujf-grenoble.fr/content/story>) (Fig. 4), the hospital’s chief doctor asks the students to write an essay. These essays are actually corrected by the teacher, but the fact that the comments are delivered by the chief doctor gives them more weight and eliminates remonstration (Ney and Balacheff 2008).

A Means to Evaluate, Track, and Provide Feedback

Finally, Learning Games offer the technical means to track the student’s actions and automatically evaluate certain skills, a feature which is very important in higher education and professional training (Carron et al. 2008). These tracks can also be analyzed in real time and presented on a monitoring platform for teachers and students themselves. Finally, these tracks can also be used to automatically adapt activities according to the learner’s level in order to keep him or her in a state

of constant motivation (Oostendorp et al. 2014). For example, the *V3S* Virtual Reality training platform offers dynamic situated feedback and progressive learning scenarios by adapting the complexity of the situations to the learner's activity and level (Barot et al. 2013). The *Reviattech* simulators (Fig. 5) also analyzes the usage tracks to provide personal feedback on technical and nontechnical skills (Huguet et al. 2016).

Current Research Questions

Learning Games have much to offer for higher education. However, there remain a number of important issues that need to be addressed before university teachers and professional trainers willingly adopt them. In this section, some of the current limitations and major research questions related to the specificities of Learning Games in higher education will be identified. First of all, research on methods to facilitate the design of custom Learning Games for specific higher education skills will be discussed. Then, the latest research on how to help university teachers resist the skepticism of their students and colleagues when they want to use games in their classes will be presented.

Methods and Tools to Create Custom Learning Games

Specialized websites offer access to Learning Games libraries (Serious Game Classification, <http://seriousgameclassification.com>, GooseChase EDU platform, <https://www.goosechase.com/edu/game-library/>, S'cape <http://www.scape.enepe.fr/>). They allow teachers to both find existing Learning Games, they can integrate into their courses, and to share their own Learning Games. These libraries are quite successful with middle school teachers because there is a large body of teachers that are interested in the same learning content and therefore have the same educational needs. In higher education, however, the curriculum is not as precise, and

Games in Higher Education, Fig. 5 Reviattech simulator for learning technical procedures and social skills. (Source: <https://reviatech.com>)

teachers create their own pedagogical activities. In this context, it is very difficult to find Learning Games that fit all their requirements.

In order to help teachers create their own custom Learning Games, several researchers have proposed methods and tools such as *ScenLRPG* (Mariais et al. 2012), *Player-VG* (Padilla Zea et al. 2011), and *LEGADEE* (Marfisi-Schottman et al. 2010) to help them communicate and collaborate with game experts.

Although working with game designers is ideal, it is often too costly and complicated to organize. Teachers can therefore use Learning Game authoring tools, which allow them to create digital games on their own, without any computer programming skills. Here are a few examples of authoring tools for specific Learning Game types: *eAdventure* for creating simple point and click games (Moreno-Ger et al. 2008), *Storytec* (Mehm et al. 2010) for puzzle games, and *JEM iNVENTOR* (Karoui et al. 2017) for educational mobile treasure hunts. These editors allow teachers to become independent and capable of improving their Learning Games year after year, adapting them to the new curriculum or a modification in the student profile.

An interesting approach, also called **game modding**, consists in asking players to create new levels for existing games. This movement appeared in the gaming industry with the famous *Counter-Strike*, a “mod” of the game *Half-Life*, designed by two players (Kücklich 2005). This concept provides several advantages for Learning Games (El-Nasr and Smith 2006). The first advantage is that students are much more likely to create the type of game that they like when following the latest trends (escape games and choose-your-own-adventure-type games). The second is the fact that the students will need to acquire a deep understanding of the knowledge and competencies that should be integrated into the Learning Game. Thirdly, teachers then have a large selection of Learning Games to choose from or build on for their future classes.

These methods and authoring environments have certainly facilitated the creation of custom Learning Games, but the process remains very complex and time-consuming for results that are not always satisfactory. Even though the authoring

tools allow teachers (or students) to create their own Learning Games, it is very difficult for them to imagine a gameplay that is fun and that also serves their pedagogical objectives. They might therefore use game mechanics that are not at all adapted to their educational goals. For example, the latest trend is to create educational escape games, even though its core game mechanics (time pressure, mini-puzzles, stress) does not create the right conditions for learning. This type of game, however, is a well-adapted alternative to a quiz in order to verify if the students have understood targeted concepts. The know-how required to select the best game mechanics and create a pedagogically effective Learning Game remains difficult to pinpoint, even for experienced Learning Game designers.

Help Teacher Convince Game Skeptics

The negative perception of games in higher education is an important issue. While some university teachers have never been more enthusiastic about Learning Games, the majority remain very skeptical or even openly opposed to such teaching methods, which they see as a waste of time. In this context, it is very difficult for teachers to try using Learning Games, if they are not 100% convinced it is going to work. This implies knowing about game mechanics, the way they can be used to attain educational goals, and having several successful examples of Learning Games in mind.

Half a dozen MOOCs on Learning Games and gamification have recently been put online to help teachers acquire such knowledge. For example, MIT offers a MOOC entitled “Design and Development of Games for Learning” (<https://www.mooc-list.com/course/design-and-development-games-learning-edx>), the University of Rotterdam offers a MOOC on Serious Gaming (<https://www.coursera.org/learn/serious-gaming>), and the University of Pennsylvania offers a MOOC on gamification (<https://www.coursera.org/learn/gamification>). Le Mans University (<https://lium.univ-lemans.fr/en/ludifikaction/>), in France, also offers a course to help teachers create their own Learning Games with the help of pedagogical engineers.

The student’s skepticism toward games can be changed if the teachers clearly explain the educational objectives of the Learning Games and why

they have chosen to use a game instead of a classical teaching method. There is a difference between mastering the rules of a game and understanding the educational concepts embedded in it. This is why a phase of reflection and debriefing is necessary after the Learning Game (Garris et al. 2002). This debriefing serves several purposes such as clarifying the educational purpose of the Learning Game (Aldrich 2005), fostering meta-cognition (Lederman 1992), and facilitating knowledge transfers to other domains and real situations.

Some teachers push the concept even further by asking their students to write an “astonishment report” on their experience playing the game and the skills they acquired. This concept is inspired by management methods (Vigier and Bryant 2009). The evaluation of the students is based on the quality of their essay and not on their actions in the Learning Game. This evaluation method seems effective as it allows the students to learn, without being penalized by errors made in the game, and encourages post analysis and self-reflection on the learning outcome.

Educating teachers about game mechanics and how they can be used for teaching and encouraging them to brief/debrief their students are both good ways to help teachers convince Learning Game skeptics among their students and colleagues. However, the best way to convince these skeptics is to provide hard proof that Learning Games enhance learning. The question of evaluation is extremely complicated and has yet to be dealt with. The usual pre- and post-knowledge tests, carried out with a control group, that does not play the Learning Game, contain too many variables and can easily be flawed.

Introduction

This entry presents an overview of advanced technologies to support teaching and learning. The use of innovative interactive systems for education has never been higher. Far from being just a trend, the objective is to use the current technology to cover educational needs and create relevant pedagogical situations. The arguments in their favor are generally their positive effects on learners' motivation and the necessity to provide learning methods adapted to our growing digital culture. The new learning technologies and emerging trends are first reviewed hereunder. We

thus define and discuss learning games, gamification, simulation, immersive environments, and other emerging technologies. Then, the current limits and remaining scientific challenges are highlighted.

Learning Games

The use of games in education is not a novelty. Humans have always used games to teach young people. However, for children growing up, education becomes less and less fun. The Serious Game approach changes this trend by arguing that the game remains a pedagogical means that can be useful at any age.

The term Serious Game can be used to cover a wide variety of systems. In its broadest definition, Serious Games are games used for purposes other than mere entertainment (Susi et al. 2007). The serious intention can be educational, informational, commercial, or ideological, for instance. When the main goal is to favor knowledge learning or competencies building, the term used is Learning Game. These games can be computer supported or not. Thus, Learning Games can be played using cards and other materials (board games) or using computers, tablets, or smartphones (digital games).

The main benefit of game-based learning is the user's motivation linked to the inherent goals of the game whose fulfillment is a source of satisfaction and rewards. So the game goals motivate the player's actions. Moreover, above all, a game has the specificity of being different from the real world, and players being able to act without fearing the consequences of their actions. Users can try and immediately see the impact of choices. According to the feedback, players can learn and develop abilities. The main educational approach is therefore active learning; the game allows the learner to decide and act within a set of game rules. For example, in the Learning Game *Refraction*, learners have to split a laser into several beams in order to redirect fractions of the original full-strength laser to power spaceships (Fig. 1).

This puzzle game helps students to learn and apply the concepts of basic fraction manipulation in mathematics.

With games, learning occurs through interactions with objects, places, and other people (collaborative learning). Finally, emotion is another important pedagogical factor. The universe and the narration of the game contribute to engage learners by making them feel emotions. Game-based learning is definitely a powerful means to take into account the game and digital culture of the new generation of learners, characterized by a relatively short attention span and a preference for exploration and discovery.

The educational purpose of a Learning Game can also be achieved through a debriefing. Often conducted with a teacher, debriefing sessions allow to get out of the game and facilitate the transfer of skills to other situations. The role of the teacher is also considered to be important to animate the game situations and to monitor the learners.

Actually, a wide variety of learning games can be found. For instance, location-based games are played on mobile devices and are useful to promote situated learning. Educational Alternate Reality Games (ARG) are based on transmedia storytelling to propose a social experience to learners who need to collaborate to accomplish activities and solve problems. In this kind of games, learners are asked to coordinate real-life activities (finding objects, talking to characters, etc.) and online activities (watching video, responding to emails, etc.). As another example, Epistemic Games make it possible for learners to learn to think in innovative ways by playing the role of professionals while learning knowledge and abilities they apply in the game (Shaffer 2006).

Nevertheless, most educators and teachers have not been trained in the pedagogy of gaming. The use of games in the classroom implies a new paradigm for the student-teacher relationship and raises many technological questions that most teachers are not ready to face. In any case, the support of school technical staff is crucial for the installation and running of the games.

Games, Simulations, Immersive Environments, and Emerging Technologies, Fig. 1 Refraction: a puzzle game to learn fractions. (Source: centerforgamescience.org)

From the point of view of the creation of learning games, inevitable technical issues are raised. The development of the game must ensure that the proposed interactions are in line with teaching expectations. So teachers need to be part of the design team. Another approach exists with the provision of authoring tools that allow teachers to create learning game without coding. This possibility is detailed later in the part dealing with research questions.

Gamification

Turning a learning environment into a serious game requires a complete redesign, which is very expensive and time consuming. An easier solution is to gamify a course by adding game design elements. In a general way, gamification consists in using game components in non-game contexts. This approach is used in various domains such as marketing, health, architecture,

and crowdsourcing. In education, gamification relies on game design features embedded in a learning situation to foster student motivation (Deterding et al. 2011). The most common game elements are: points, badges (trophies symbolizing a task fulfillment), leaderboards, object collection, etc. A good example of gamification is *Classcraft*, a platform to gamify classrooms (Fig. 2). With *Classcraft*, teachers and students play together in the classroom a role-playing game. Students can level up, work in teams, and earn powers that have real-world consequences (e. g., switch seats, choose the order during presentations, etc.).

The Learning Management Systems (LMS) propose more and more often gamification features. For instance, some plug-ins can be integrated to Moodle to gamify courses: badges, achievements, points, etc. Some other platforms even build gamification into the bones of their learning solutions (i.e., The Academy LMS, Paradiso LMS, etc.). In any case, these systems require

Games, Simulations, Immersive Environments, and Emerging Technologies, Fig. 2 Classcraft, a platform to gamify classroom activities. (Source: classcraft.com)

time from the teachers to set up the game features they want to set up for their students.

Simulation

Simulations should be distinguished from Serious Games. A game can be based on a simulator, but this is not necessarily the case. Digital simulations are based on virtual environments that replicate, with a high degree of fidelity, real-life phenomena, or situations. For instance, simulators in STEM fields (science, technology, engineering, and mathematics) rely on specific models and equations (electronics, physics, etc.) to calculate results with a given set of input data. A simulator gives the opportunity to carry out experiments by modifying inputs and observing the outputs generated by the system. For example, with *Newton*, users can manipulate 3D virtual objects and investigate real-life physics experiments interactively (Fig. 3).

Even if simulations cannot replace practical learning with real devices, they offer the possibility to train without costly materials and avoiding potential dangers. Simulators can also be used in non-STEM fields to represent a global behavior or

situation. For example, simulators exist to train people to apply procedures or to use the right sales method in front of customers.

As said before, some Serious Games integrate a simulator, i.e., a model of a real-world phenomenon (in mechanics, physics, economics, etc.). For instance, *Physica* is an example of serious game based on a physical simulator. In this case of simulation-based serious game, a scenario is designed according to pedagogical objectives to be achieved. Another example is *Pulse!!*; a simulation-based learning game for health care professionals which allows them to train and practice without the risk of harming patients (Fig. 4). Learners work in a virtual hospital where they respond to emergency situations, diagnose, and treat patients as they would in the real world. The game adds a narration to the simulator and sets goals or actions to be achieved.

Nevertheless, the situation does not necessarily need to be realistic in a serious game: metaphorical situations can also lead learners to build skills. For instance, a fiction science scenario can help to learn concepts in sustainable energy. The skills developed can be meaningful for learners even in an imaginary situation, far from reality. There is no need to have a model to reproduce situations

realistically; the game can be based on a pre-defined scenario.

Immersive Environments

Virtual Reality (VR) is a computer technology that uses devices and three-dimensional interfaces to simulate the user's physical presence with realistic images, sounds, and other sensations. The key elements in experiencing virtual reality are a virtual world, immersion, sensory feedback (responding to user input), and interactivity (Sherman and Craig 2002). Interactivity not only refers to the user interacting with the system but also to multiple users interacting together and collaborating within the same virtual space.

Several devices can be used in VR. Head mounted display (HMD), goggles with a screen in front of the eyes, are the most popular solution, and less and less expensive. More sophisticated VR systems exist, for instance, CAVE (Cave Automatic Virtual Environment) are immersive virtual reality environments where projectors

display multiple images on the walls/floor/ceiling of a small room (Cruz-Neira et al. 1992). For the manipulation in these virtual environments, the possible devices range from simple joystick to specific data gloves or haptic feedback systems.

Compared to traditional Technology-Enhanced Learning (TEL) systems, VR environments make it possible to include the body in the learning process, and more generally to integrate sensorimotor and proprioceptive aspects, thanks to rich interaction modalities. It is thus possible to implement learning methods that immerse the learner into a given context. For example, immersive virtual environments are used for adult lifelong training in complex domains where technical systems are difficult to apprehend and human factors are critical. In I3TE (Immersive 3D Training Environment, Eon Reality), plant operators and engineers have the opportunity to train together in the same environment by reacting to a wide range of situations (Fig. 5).

By definition, virtual reality applications are often based on a simulation. Immersion of the learner can greatly facilitate situational learning.

Games, Simulations, Immersive Environments, and Emerging Technologies, Fig. 5 Training of operators in a CAVE (iCube) with the environment I3TE. (Source: eonreality.com)

Nevertheless, the fact of using virtual reality is not enough to ensure learning, just as visual fidelity is not a guarantee of pedagogical effectiveness (Bossard et al. 2008). A reflection must be made both on the didactic situations and on the scenario. Again, gaming scenarios can be used to motivate the player to improve skills. As discussed further, research questions remain in this field.

Emerging Technologies

In last years, devices and sensor technology evolved considerably, while costs of hardware and development platforms decreased quickly. Augmented and Mixed Reality technologies bring new opportunities for education and training. Augmented Reality (AR) overlays the real world with virtual content to create an immersive environment placing the learner in real-world context and engaging all senses (Bacca et al. 2014). More generally, Mixed Reality (MR) was defined as a continuum between real world and virtual world (Milgram and Kishino 1994). The objective is to enrich a situation based on the real world or add realism in a virtual environment. This objective can be achieved using many devices such as screens, cameras, see-through glasses, mobile devices, and tactile or tangible interfaces. Some research on the integration of mixed reality interactions into educational applications have highlighted their potential, mainly to improve the anchoring of learning and positioning learners in authentic situations (Egenfeldt-Nielsen 2006).

For example, the *wekit project* aims at experimenting new forms of interaction for professional training (Fig. 6). The idea consists in capturing expert experience and sharing it with trainees during task-sensitive augmented reality. A pilot study is currently conducted in the field of aircraft maintenance in order to present data in context and augment performance (Guest et al. 2017).

Tangible User Interfaces (TUI) can also be used for advanced interactions in educational activities. With TUI, users can interact with a digital environment through physical objects. For instance, TUI can be coupled with interactive tables, taking advantage of the user ability to manipulate physical objects. Another recent trend concerns learning games that mix real objects (cards, game pawns) and virtual environments (game board on tablets or smart phones).

Using principles derived from embodied cognition, TUI can increase learning performance by offering sensory perception and feedback (Skulmowski et al. 2016). Thus, the relationship with objects is not only physical but has also a cognitive dimension. It impacts the way users perceive the environment. The importance of movement and manipulation has often been demonstrated in children education.

Current Limits and Research Questions

In all types of learning environments described above, important research questions remain.

Games, Simulations, Immersive Environments, and Emerging Technologies,
Fig. 6 Aircraft maintenance training with the use of AR technology in the *wekit project*. (Source: wekit.eu)

Some scientific locks are common; others are more specific to a category of systems. Overall, the main problems concern the cost of designing and building these environments because of their complexity and the high level of interactivity they offer. Budgets can very often be substantial, from several tens of thousands of dollars to several million for some applications (for example, Pulse!! has cost ten million dollars).

Beyond budgetary constraints, the aforementioned systems generally target a relatively small audience by addressing the development of specific knowledge or skills. It is therefore not easy to have a “return on investment” and their creation is therefore risky. In order to avoid risk-taking and reduce costs, it is desirable to be able to reuse some elements: scenarios, components, resources, game engines, simulation engines, interaction techniques, etc. Unfortunately, this capitalization has so far been poorly supported. The main obstacles are related to interoperability difficulties, whether technical (software engineering issues) or semantic (educational science issues).

In order to meet this need for capitalization and also to involve teachers and subject matter experts in the process of designing learning environments, research works have been conducted for several years to propose authoring tools (Murray et al. 2003). The main purpose of an authoring tool is to enable people without any programming skills to design and deliver instrumented learning activities. An authoring tool in education is thus used to create educational environments, ranging from simple resources (content, exercises, etc.) to more complex systems (serious games, simulation, etc.). In the latter case, authoring tools mainly focus on specific situations, such as *e-Adventure* (Torrente et al. 2010) to design point and click adventure games (Fig. 7), *JEM iNVENTOR* (Karoui et al. 2017) to create mobile learning games, or *SimQuest* (www.simquest.nl) to configure physics simulations. The difficulty of these research works is not only technical but also concerns the support of pedagogical design. It is therefore essential that authoring tools guide teachers by providing them design methodologies

related to the kind of interactive learning environment they want to use with their students. The major challenge lies in providing an authoring tool that is, for a teacher, simple enough to quickly create interactive activities and rich enough to set up situations adapted to a particular learning subject and audience.

A research topic to be developed concerns the interoperability between authoring tools. Since they are often specific to the design of specific resources or activities, it would be useful to combine them to propose richer learning situations. For instance, we have seen before that a simulation environment can integrate both real and virtual objects, used in conjunction with a game scenario. The complexity of this type of environment can difficultly be managed without connecting existing authoring tools.

Another research question is related to the use of computer traces that can be collected in interactive learning systems. In these computerized environments, it is possible to gather data on the actions carried out by each learner. Advanced interaction devices also make it possible to have information from sensors (positions, gestures, etc.). Data analysis or learning analytics techniques can then be applied to provide semantic information from these raw data. Several uses of these traces are then possible:

- To automatically adapt activities, for instance, in the case of learning games, the challenge is to be able to adapt the level of difficulty according to the learners’ skills in order to keep them in a state of motivating flow (van Oostendorp et al. 2014).
- To give feedback to students, the objective being to help them to evaluate their actions and encourage reflexivity. The aim is also to make the learners step back from the situation and thus encourage the transfer of learning to other contexts. On these issues, artificial intelligence can lead to major advances. For example, chatbots are already being used for educational tutoring or individual didactic support (Soliman and Guetl 2013).

Games, Simulations, Immersive Environments, and Emerging Technologies, Fig. 7 e-Aventure, an editor to create serious adventure games. (Source: e-adventure.e-ucm.es)

- To provide pedagogical indicators in order to enable the teacher to monitor the game and immersive activities (individual and collective). In such settings, educational monitoring and intervention are not easy; the teacher may lack information about the tasks performed by learners. So, the teacher activity support must be a concern before, during and after the instrumented learning activity. On this topic, interesting research concerns technologies to support the teacher in the orchestration of learning activities. For instance, tangible interfaces can be used for the real-time management of events and activities in a classroom (Dillenbourg and Jermann 2010).
- To inform the designers, or the design team, of the interactive learning activities to help them to redesign educational scenarios and tasks (re-engineering approach).
- To provide researchers with data for the scientific evaluation of the systems (impact on learning, motivation, usability, etc.).

In connection with this last point and to conclude, it would be important in the future to develop studies showing what kind of activities and what kind of computer support or Human-Computer Interactions should be implemented to promote certain types of learning. Of course, in this area it is important to keep some design

freedom, but recommendations, best practices, and reproducible methods could helpfully guide teachers and instructional designers.

Gamification: A Definition

Coined in 2008, the term gamification has not yet reached a consensus from the academic community, and, depending on the considered authors, two categories of definitions are proposed. A first category of definitions is based on the etymology of the term. Gamification consists of “making or fabricating a game,” i.e., applying game mechanics and using game elements such as badges, points, bonuses, and leaderboard in order to convert a nongame context into a game-like activity. This definition is based on a point of view about what is a game that falls within “essentialism,” i.e., the functions of a game result from a set of attributes. A second category of definitions is currently emerging. This category of definitions considers gamification to be a process focused on the player experience. This process consists of the implementation of motivational affordances grounded in game design principles and aiming at fostering “gamefulness” or “gameful experience.” These latter definitions insist on the subjective nature of the experienced value of a game. Play is considered to be based on activity and meaning originating from the player. Gamification results in (internal) psychological and (external) behavioral outcomes because the focus is on influencing learning performances, attitude, and/or behavior. From a learning perspective, gamification is considered to provide positive effects by fostering the learner engagement into epistemic activities. However, potential negative outcomes, such as increased competition, are also reported.

Introduction

The term gamification (coined as “game-ification”) appeared in 2008 in the digital media economic sector (Deterding et al. 2011a). In a blog post following the Social Gaming Summit, Bret Terrill (2008) describes the word as “taking game mechanics and applying to other web properties to increase engagement.” Since then,

the term has been popularized in different conferences (Google Tech Talk) by Zimmermann in 2010 and Amy Jo Kim in 2011 (Kapp 2012). Gamification, as an emerging concept, has also attracted considerable attention of the educational research community, and gamification is becoming a popular subject for academic inquiry (Hamari et al. 2014). Besides that, gamification is often incorporated in persuasive technologies to influence attitude and behavior.

Etymologically, the word gamification is based on the Latin verb *facere* (“to make” or “to fabricate”), reflecting the idea that it is possible to “create a game.” The concept emerged in the digital media economic sector (Deterding et al. 2011a) but was early adopted by educators. The concept has close relationships with edutainment and game-based learning. However, edutainment is used in a broader sense and is not limited to game principles. Indeed, edutainment also refers to media for leisure such as television. Gamification is generally considered differing from game-based learning as gamification is more about applying game design principles to nongame contexts than using individual video games.

In a usual gamification process, gameplay elements are implemented in real-world processes or activities to stimulate behavior (Deterding et al. 2011a). For example, Classcraft (see the example below) consists of implementing loss or gain of points, powers, and privilege as well as random events for classroom management.

Recent definitions, characteristics, and perspectives about gamification (Lieberoth 2015) and the implemented motivational affordances are discussed in section “[Gamification: Definitions and Characteristics](#).” The resulting psychological and behavioral outcomes mentioned in the related literature are discussed in section “[Gamification and Learning, Attitude and Behavior Changes](#).” Section “[Examples](#)” provides some examples of gamified contexts in secondary and higher education, and regular households. Section “[Criticisms Leveled](#)” is dedicated to stress the ongoing debates on gamification and its use for educational

purposes. Current trends in the gamification field are highlighted in section “[Current Trends in the Gamification Field](#).”

Gamification: Definitions and Characteristics

The emerging scientific literature describes gamification firstly as game mechanical elements and secondly in psychological terms. According to the first perspective, Terrill (2008) describes gamification as “taking game mechanics and applying to other web properties to increase engagement.” Since then, several definitions have been suggested, such as “the use of game design elements in non-game contexts” (Deterding et al. 2011a) and “using game-based mechanics, aesthetics, and game thinking to engage people, motivate action, promote learning, and solve problems” (Kapp 2012, p. 1). Game elements (or game design elements) are the game components or the objects that the player interacts with. Some game elements enable rewarding the player (points, badges, bonuses, leaderboard, etc.), while others are linked to the gameplay (limited time, game levels, etc.). Game mechanics are methods invoked by agents for interacting with the game state (Lieberoth 2015) such as the use of a dice as randomizer, movement of playing tokens, or acting out roles. Game mechanics create emergent gameplay. Game mechanics are diverse and fall into several categories that are used to categorizing games (Seaborn and Fels 2015).

However, basing definitions of gamification on a set of game elements or game mechanics is problematic. There do not seem to be a basic set of elements that are unique to games, and game mechanics might be not specific to games (Huotari et Hamari 2017). As a result, according to a second perspective, gamification is considered to be a process focused on the player experience. In that case, gamification is grounded on two core concepts: motivational affordance and gamefulness. Motivational affordances refer to actionable properties between an object and an actor (Gibson 1977). The user is not forced to act upon these

objects, but they demand interpretation by the actor. Characteristically, they open the possibility for the occurrence of motivational needs and emotional states. Thus, rather than focusing on game elements that the user has automatically to interact with, gamification is considered to resulting from voluntary player’s interactions with the game. Play is considered to be based on activity originating from the player (Sanchez and Mandran 2017). The term “gamefulness” or the expression “gameful experience” is used in this context to describe an experiential condition that is unique to games. This experiential condition makes possible for anyone to recognize a game. Play is considered to be based on activity and meaning originating from the player. Therefore, *gamification* can be defined to be *the implementation, in nongame contexts, of motivational affordances grounded in game design principles and aiming at changing the meaning of the situation and fostering gamefulness where the focus is on influencing learning performances, attitude, and/or behavior*.

A way out of the contrast we signaled is to assume that gamification presupposes the first as well as the second perspective mentioned which is more or less the case in the definition of Seaborn and Fels (2015): *gamification is the intentional use of game elements for a gameful experience of non-game tasks and contexts* (p. 17). Game elements are, for this definition, patterns, objects, principles, models, and methods directly inspired by games.

Gamification and Learning: Attitude and Behavior Changes

In recent years, a number of studies have been conducted on the effects of gamification on learning processes through integration of several game elements (e.g., badges, leaderboards, points) in the learning environment (Caponetto et al. 2014, Dichev and Dicheva 2017). Most studies conducted in the education area on the effect of gamification focus on two variables: learning performances and learners’ motivation.

Regarding learners' performance, most studies show a positive impact of gamification as the integration of one or several game elements. De Marcos et al. (2016) compared educational game, social networking, gamification, and social gamification approaches in their impact on learning performances in an undergraduate course. They define social gamification as the combination of gamification and social networking to create compelling socially driven user experiences (e.g., blogging, questions and answers, liking, friends, personalization (status/visibility)). They showed that social gamification induces better results for all types of assessments. Da Rocha Seixas et al. (2016) were also interested in the impact of badges on learners' performances, and the results indicate that their performance was improved. Landers et al. (2017) studied the impact of leaderboards on task performance and highlighted the interest of this gaming feature in supporting goal setting. The results obtained by Domínguez et al. (2013) are more nuanced considering the impact of gamification according to the type of learning task. The study conducted in a university course showed that gamification had a positive impact on the students' performances in practical assignments and on overall performance, but it had a negative effect on students' performance in written assignments and participation in class activities, although the students' initial motivation was higher.

Regarding learners' motivation, we can observe differences in the results obtained in several studies (Seaborn and Fels 2015). For instance, Hamari (2017) focused his study on the use of badges to increase learner engagement in the learning activity consisting of getting used to working with an application for online communities where one can share goods and services. Results show that learners who used badges were significantly more likely to post trade proposals, carry out transactions, comment on proposals, and generally use the service in a more active way. However, a related study conducted by Hanus and Fox (2015) showed that integration of a leaderboard and badges induces a lower level of motivation and lower

final exam scores for students, thereby showing a negative effect of this gamification feature.

Beside the education area where the focus is on learning performances and learners' motivation, another area of gamification is the persuasion area where the focus is on influencing attitude and behavior. The "educational component" is leveraged to persuade people to change their attitude or behavior (Bogost 2007; Fogg 2003). It is not surprising that this type of gamification has its roots in the corporate sector because changing attitude and behavior is one of the core activities of the marketing discipline. There are several studies that have reported changes in behavior when gamification strategies were used, but only a few report changes in attitude. Seaborn and Fels (2015) analyzed empirical findings of 31 studies. They reported that in 61% of the studies, gamification had a positive effect, but 39% had mixed results. In almost all cases (97%), the aim was to influence behavior of the participants. Unfortunately none of the 31 studies reports about attitude changes. Only behavior, learning performances, and/or engagement was measured. Hypothetically we would expect that attitudes should change if behavior changes by using gamification. An attitude is an evaluation of an object of thought. The focus of an attitude may comprise anything a person holds in mind, ranging from the mundane to the abstract, including things, people, groups, and ideas. Most researchers agree on this core definition according to Bohner and Dickel (2011). They also mention that researchers have long been using self-report scales, which directly ask a respondent to evaluate the focus of an attitude by checking a numeric response on single or multiple items. It is possible that the limitation of this method in measuring attitudes is the reason for researchers of the 31 studies not to examine attitudes. In another literature review of empirical studies on gamification of Hamari et al. (2014), psychological outcomes of 12 studies are reported. These psychological outcomes refer to perceptions, motivational affordances, and engagement toward a gamification application and not to the behavioral context where this

application is aimed at, for example, preserving energy in the household. Hamari et al. (2014) state that in only four studies, user qualities were believed to have an effect on attitudes toward gamification itself. All this suggests that there is a lack of research concerning attitude change by using gamification techniques. An exception is a study of Smith (2017) where a positive attitude shift is reported in a condition where students attended a gamified statistics course. Another one is reported by Bonvin and Sanchez (2017). Their study, based on the records of students' behavior of three classes, shows that gamification fosters collaboration among secondary students. Lastly, there are some studies – all on the area of sustainability – where attitude change using gamification is reported. Fijnheer et al. (2016) analyzed these (eight) studies where a gamified persuasive household energy application was developed – by implementing real-world processes *in* the design – in order to influence energy consumption of households. All studies report a positive behavior change, seven studies report a positive knowledge change, and six studies report a positive attitude change toward energy saving as well. The authors suggest the following gamification elements to be effective: gameplay (six studies), feedback (five studies), team

play and social component (three studies), and competition (three studies).

Examples

Since gamification emerged, the concept has been applied in various educational contexts (De Sousa Borges et al. 2014; Ortiz-Rojas et al. 2017) from primary to higher education. According to these meta-reviews, there is a majority of papers on gamification for higher education. Studies on gamification for primary and secondary education are less frequent (ibid.). Gamification has been implemented into Massive Online Open Courses (MOOCs) (Chang and Wei 2016), training, and lifelong educational programs. In the following, we describe three examples of gamified contexts.

Gamification of Classroom Management with Classcraft

Classcraft (Sanchez et al. 2016) is a mobile web-based application for classroom management (Fig. 1). Since Classcraft launched, more than 2.5 million active accounts have been created, and ongoing analysis demonstrates the game's efficiency in terms of students' collaboration (Bonvin and Sanchez 2017). Classcraft

Gamification, Fig. 1 Screenshot of Classcraft©

transforms the classroom into a role-playing game. Students are placed in teams and play as mages, warriors, or healers. In order to acquire powers, the players must meet teacher expectations by, for example, arriving to class on time, doing homework, and helping other students. Depending on its behavior, the player will win or lose gold pieces (GP) needed to customize their avatar, health points (HP), experience points (XP), and action points used to acquire powers. Randomness is another game mechanics that is leveraged in *Classcraft*. Once a week, the class starts with a random event that may have a positive or negative impact, such as losing or winning points, on every team. Randomness also manifests itself when, having lost all his points, the player must throw the “cursed die.”

Students progress in the game by exhibiting positive classroom behavior and attitudes such as collaboration with peers, thus acquiring powers and progressing their avatar. With *Classcraft*, a student who comes to class 5 min late may use the power of “invisibility” to avoid punishment. If the student does not have this power, the teacher, as gamemaster, deducts points. The loss of too many points causes death, which may mean a school detention or another punishment, depending on the rules set by the gamemaster. Students can also use their powers individually or collaboratively. For example, mages are very powerful and can often use their abilities to benefit their entire team. *Classcraft* is intended to foster student collaboration within teams. It is also designed to motivate students to comply with classroom rules of conduct.

Gamification and Enhancement of Sustainability

The inclusion of reality by using gamification principles in a gamified persuasive application can be an effective means to change people’s energy-related attitude (Fijnheer and van Oostendorp 2016). When people are highly engaged, they are apt to adopt the attitude that is promoted in the application (Ruggiero 2015). This can lead to a higher awareness of relevant factors involved in, for instance, energy saving. In effect, attitude may positively change and, as

such, subsequently trigger a change in energy-saving behavior itself. The assumed chain of events, higher awareness (more accessible knowledge)-attitude change-behavior change, is what gamified persuasive applications try to influence (Aronson et al. 2013; Chen and Chaiken 1999; Soekarjo and van Oostendorp 2015). The application *Powersaver* (Fijnheer and van Oostendorp 2016; Fijnheer et al. 2016) is used as an instrument of a larger research project that will give insight into what the influence of playing in the real world is on attitudes toward sustainability and on sustainable behavior in the long term. The focus is specifically on energy consumption in households by means of electricity and gas usage. The target is to contribute to the stimulation of individual sustainable behavior by studying how gamification can be a positive incentive for people to change their behavior regarding energy use at home. Therefore several gamification elements such as missions, levels, quizzes, narrative, competition, badges, and feedback are implemented. It aims to study whether transfer from game play to real-life behavior has a long-term character (Gustafsson et al. 2009a).

Powersaver (Fig. 2) is used in a household whereof the whole family is involved by implementing the gamification element cooperation. The navigation by the user is done by point and click on a tablet. *Powersaver* is basically an Internet page. It starts with an introduction of a story. This constitutes the narrative gamification element. A family arrives at a dilapidated country house where a professor had caused a failed experiment. Avatars of the family members are the central characters of the narrative. The family composition in the application is customized to the household. The family enters the main hall of the house that contains several locked doors. Behind each door a room is situated where a character in the form of a confused electrical device is placed. A cat (former pet of the professor) called Kyoto guides the family in the narrative. Every mission session the family is asked to enter a preselected room. Before the door opens a quiz has to be played. A quiz contains questions that will prepare players for the missions that are occurring in that specific room. When the family

Gamification, Fig. 2 Screenshot of powersaver

enters the room, a character in the form of a device that is in a confused state is shown. The family has to accomplish, in one and a half or two and a half day, missions to help the device to get in a normal state. All missions (e.g., washing clothes on low temperatures) take place in the real world. In time the missions are getting more difficult. The total period of using the system is 5 weeks. *Powersaver* has 13 missions, 8 quizzes, and an end battle/scene. These missions are an important gamification element and represent the real-world processes that are incorporated in the persuasive system. A real-time connection between the household energy meter and computer server is accomplished by data loggers with an Internet connection. Energy consumption is monitored a month before the application starts to set a good baseline of average energy consumption. Another gamification element is feedback that users are getting on energy use and savings, the results of the quizzes, and achievements of completed missions that are displayed with badges. Another implemented gamification element is competition. A household is in competition with seven virtual households, but assumes to play against real households.

An Example from Higher Education: Brewing Beer

Brom et al. (2017) studied with university students a complex process (brewing beer) in a computerized simulation. In a 2-h interactive simulation, they learned how to brew beer. The simulation focused on the boiling, fermenting, and conditioning phases of the brewing process. The graphical interface (Fig. 3) showed different panels, e.g., an animation panel showing the content of fermentation vessels, graphs, and histograms showing the amount of ingredients, buttons for controlling the processes, etc. They examined adding several gamification elements to the simulation like providing a clear game goal, increase of the freedom of choice (of tasks to work on), points, virtual currency, and including verbal feedback.

No differences between the gamified simulation and control versions were detected nor concerning learning outcomes nor concerning affective-motivational aspects. Also 1 month after playing the simulation, no differences were found. However, one significant difference concerned perceived difficulty: the gamified

Gamification, Fig. 3 Screenshot of graphical interface (Brewing Beer)

simulation was *perceived* to be easier than the control versions. Maybe the gamification seduced learners to a light learning conception with the risk to engage only in superficial learning, and failing to help learners to engage in deep learning (Conway 2014).

The null results of this study may indicate that the gamification did not succeed in increasing learning nor motivation perhaps caused by increased distraction due to the many extra details in the user interface. An important implication of their study is that one should be careful with adding gamification elements (Conway 2014; Seaborn and Fels 2015). Researchers should also consider individual characteristics like attitude toward ICT, ICT experience, and background knowledge.

Criticisms Levelled

– Gamification Versus Ludicization

Etymologically, the word gamification reflects the idea that it is possible to “create” or to “fabricate” the game. Therefore,

gamification is considered to be an automatic and non-problematic transformation (Silva 2013) often referred to as *pointsification*, i.e., gamification that exclusively relies on points, badges, and leaderboards (Kapp 2012). However, right in 2011, Deterding et al. (2011b) state that gamification consists in addressing playfulness (the experiential and behavioral dimensions) and in using these dimensions for the design of structures with ludic affordances. As a result, some authors suggest to adopt the word *ludicization* in order to focus not on the artifact but on the situation that takes place when an individual accepts to play (Genvo 2013; Sanchez et al. 2016). Therefore, play is considered to be *performative* (Sanchez and Mandran 2017), and play depends on the *lusory attitude* (Henriot 1969) of an individual who accepts the arbitrary and artificial rules of the game. According to this approach, there is no specific game element that can be used to make a game (as supposed by gamification), but it is possible to subtly combine elements in order to design a learning context where play can take place

(ludicization). The term ludicization is based on *ludus*, the Latin root of ludicization, which means both game and school work. In addition, the suffix “-icization” does not mean that it is possible to “create” the game, as suggested by the suffix “-fication” (*facere*) of gamification, but primarily that it is possible to transform the situation (Sanchez et al. 2016).

– **Short-Term Versus Long-Term Effects**

Beside the difficulties faced by researchers to assess the results of gamification, some studies show that the results of gamification may not be long-term, but instead could be caused due to a novelty effect (Hamari 2017). Due to the lack of longitudinal studies, this issue remains unclear and needs further investigations (Seaborn and Fels 2015).

– **Edutainment and the Chocolate-Covered Broccoli Approach**

Gamification is often considered to belong to the edutainment trend. Edutainment considers that educational objectives should be hidden to students or, at least, “sugar coated.” This approach is in line with the *maxime placere et docere* (to please and teach) (Horace 65-8 bc) and the humanist learning tradition expressed by Erasme (1467–1536). Criticisms expressed by Bruckman (1999) underline the risk that instructional game-based techniques that consist of just covering games over the learning content in order to make the learning content more palatable have become synonymous with the *chocolate-covered broccoli* approach of teaching (Habgood and Ainsworth 2011).

– **Behavioral Patterning and Ethics**

Gamification is a process by which end-user engagement and behavior can be shaped and directed. As a result, by applying normative constraints, gamification has the potential to be used as an instrument of coercion. Therefore, there is a risk to apply techniques leading to lose the emancipatory aim of education. This ethical issue seems not yet being addressed by researchers and is not often mentioned in research papers.

Current Trends in the Gamification Field

Although gamification is a term still used with diverse meanings and grounded on underdeveloped theoretical foundations (Seaborn and Fels 2015), research in the educational field is very active. Below, we present two current trends of research in the gamification field: the inclusion of reality by using gamification elements in a gamified persuasive application and adaptive gamification.

Inclusion of Reality by Using Gamification Elements in a Gamified Persuasive Application

Usually in gamification processes, gameplay elements are implemented in real-world processes or activities to stimulate behavior (Deterding et al. 2011a). In some research projects, a different and novel approach of integration of gamification is chosen. Real-world processes, e.g., household energy-saving activities, are implemented *in* the design of a gamified application. In this approach, situated learning experience is provided by integrating a persuasive simulation with gamification elements such as missions, levels, quizzes, narrative, competition, badges, and feedback. The learner applies his/her knowledge directly to solve problems (Gustafsson et al. 2009b) by performing tasks in the real world that are at the same time directly interconnected to the gameplay in the digital world. The inclusion of reality by using gamification elements in a gamified persuasive application can optimize the transfer of knowledge from the application to reality (Kors et al. 2015). Some gamification research suggests that the integration of serious games into real life could have positive effects on attitude and behavior (Gustafsson et al. 2009a; Hamari et al. 2014). It can be assumed that implementing real-world processes, instead of simulated/fictive processes, in a gamified persuasive application will have positive effects. It is important to note that in this novel, reversed approach, it is *not* the case that gameplay elements are included in real-

world processes. Instead, real-world processes, e.g., household energy-saving activities, are included in the application itself. *Powersaver* described above illustrates this approach. This approach tries to optimize the transfer between the digital world and the physical world. When the transfer is optimized, the application can be more effective in change of attitude and behavior (Kors et al. 2015). At the moment of this writing (November 2017), this first study with *Powersaver* is in its ending phase, and the results are promising. Households in the gamified condition have reduced up to 21% in energy consumption during the intervention and have a reduction on average of 10% in the period after the intervention. Households in a control condition that used the Powersaver energy dashboard – the Powersaver application without gamification elements – didn't change their behavior in energy consumption. So the essential difference between both conditions involved the gamification elements (Soekarjo and van Oostendorp 2015). In a recent, comparable project Casals et al. (2017) report similar positive effects.

Adaptive Gamification

Gamification in itself still lacks the adaptivity required to reach a wide range of users (Vassileva 2012) and to meet learners' game mechanism preferences (Harviainen 2014). In fact, users show different types of engaged behaviors when interacting with online environments (Bouvier et al. 2014) and different player preferences (Bartle 1996). According to Harviainen (2014), "the very elements that motivate some learners (e.g., competition) are the ones disliked by others, and also those that when taken to excess, cause problems." Research in the gamification field tends to consider the role of individual differences, for example, personality differences (McCrae and John 1992), player types (Yee 2006; Hamari and Tuunanen 2014; Monterrat et al. 2015), and demographic differences (Koivisto and Hamari 2014), in the perception and effects of the gamification process. Furthering this line of research could refine the understanding of user-related factors

(Hamari et al. 2014) and build foundations for adaptive gamification.

Still little is known on *how* to adapt game elements to users in learning environments and more generally in computer-based environments. The work conducted by Monterrat et al. (2015) is one of the first to address this issue. They integrated and adapted gaming features in a learning environment according to player types. The exploratory study they conducted showed the potential of the adaptation of gaming features for enhancing learners' motivation. This supports the hypothesis that there is a need for adaptive gamification of learning environments. In a more recent study, Monterrat et al. (2017) also showed that the users' activity can help to predict their profile that can be used for the adaptation process. In their study, the adaptation process did not improve learners' engagement as expected, but it draws a path for future research toward an adaptive approach for learning environment gamification.

Gender Difference in Self-Efficacy for Computational Thinking in K-12

Monica Banzato and Paolo Tosato

Department of Linguistics and Comparative Cultural Studies, Ca' Foscari University, Venice, Italy

Synonyms

Capacity beliefs; Computer science; Gender gap; Primary and middle school; Science education

Introduction

The introduction of computational thinking (hereafter, CT) and coding in primary and secondary schools (hereafter, K-12) is one of the novelties introduced by recent educational policies in many countries of the world. The aim is to prepare students for a world strongly influenced by information technology (Wing 2006; NRC 2010, 2011) and to encourage a culture of creation and production rather than the mere passive use and consumption of technology. At this level of education (K-12), the inclusion of CT appears to be:

- An unprecedented opportunity, as for the first time, this subject is being introduced among the curricular subjects for younger children (European Schoolnet 2014).
- A strategic challenge for educational institutions, as (1) there are still low enrolment rates

for students in the STEM area (Science, Technology, Engineering, and Mathematics) in many countries (OECD 2015a); (2) there is a large gap in inscriptions for the STEM area between males and females, to the detriment of the latter (OECD 2015b).

International research literature on computer science education continues to confirm a worrying underrepresentation of women in the information and technology sectors, with disturbing results about gender impact (OECD 2015b). The use of computers and ICT-related activities have been seen as a “male domain” in the recent past, and this interpretation still remains today, despite slight improvements in the treatment of the different genders (Pechtelidis et al. 2015).

The crucial age for the choice of studies and careers is between 13 and 17 years of age; this period presents a crossroads, in most cases with no return path, in which teenagers definitively choose what course of study to pursue. The data generally record the abandonment by girls of science subjects (such as natural sciences, engineering, and technology) to pursue other choices, usually in the humanistic field. Looking more closely at some figures (the EU area is taken here as an example), one sees that the number of female graduates is 55%; but attending to data from the scientific area, it is notable that women graduates in computer science are only 22% compared to 78% male. Even in advanced research studies, such as at PhD level, although the number of women is higher than men, they are still a numerical minority in the fields of engineering and computer science. In the workplace, the numbers drop drastically: the percentage of women responsible for IT systems is 27%, and this drops drastically (to 9.6%) among those responsible for hardware engineering. Women hold only 5.8% of senior university academic positions in the fields of information technology, engineering, and technology (European Schoolnet 2014).

Although there is a vast literature on gender difference and ICT in general, an alarm has been issued by many parts of the scientific community (NRC 2010, 2011; Grover and Pea 2013; Wing 2017) that there is an international research deficit

on CT in K-12 (which has suddenly become a curriculum subject in many countries of the world). This new area requires that investigation shift from ICT to Computer Science Education, taking into account that some areas are still untouched by gender studies, as are some other fields such as special educational needs and CT assessment for this age group. Therefore, it seems even more urgent to introduce gender analysis of CT activity on several fronts of research and educational practice, as children aged from 6 to 12 have already formed their knowledge, ideas, beliefs, and habits regarding technologies, and these experiences will show their effects, after the age of 12, in the choice of studies and careers.

Research in the educational field (and not only there) over the past 50 years has shown how critical beliefs and attitudes are to the future choices of students. It is important to know and investigate the cognitive and metacognitive aspects (functions, processes, and strategies) that are implemented in this phase of development (6–12 years). It is equally important to understand and investigate the system of values that boys and girls build around their learning experiences, including those that are not purely cognitive but also motivational and affective, such as the idea of CT a student has; the idea the student has of himself/herself in relation to this subject; his/her convictions or doubts about their ability to use coding; the security he/she has in dealing with problems in the subject and persevering over time. Clearly, there is a pressing need to achieve a lucid theoretical and practical understanding of CT learning in K-12.

This work focuses on the effects of gender differences in self-efficacy among K-12 students on their beliefs and their ability to succeed in specific situations (Bandura 1997). Given that self-efficacy is a vast area of research, some particular aspects will be analyzed in depth in the following sections: definition, dimensions, sources, measures of self-efficacy, and gender research in academic performances (see section “Self-Efficacy in Gender Difference”); finally, attention will be focused on situations related to gender in self-efficacy beliefs in K-12 students

when they are learning CT (see section “[Related Work: Computational Thinking, Gender Difference and Self-Efficacy in K-12](#)”). The conclusions are focused on the gender research recommendations in self-efficacy for CT in K-12 (see section “[Conclusion](#)”). It is important to underline that both self-efficacy and academic literacy are highly context dependent and, therefore, difficult to measure (Bandura 1997; Zimmerman 2008; Eccles 1987). However, research conducted so far shows that both of these measures influence student learning outcomes (Bandura 1997; Hattie 2012). At the point where research has arrived, presenting the state of the art on gender difference in self-efficacy for CT in K-12 is particularly difficult for the following reasons:

1. Being a recent phenomenon in K-12, this specific area is still little investigated. Given the small amount of data available, comparisons and generalizations of the results are difficult to achieve, not only because of differences among the organization of various school systems and their various sociocultural contexts but also because of different understandings of the meanings of key terms (including “computational thinking,” “coding,” and “programming”). These terms are sometimes used with separate meanings and sometimes synonymously. Their definition is still the object of heated discussions within the international community and among national scientific communities in their respective countries (NRC 2010, 2011).
2. In the research literature, there are several instruments to detect self-efficacy that have been validated internally but not externally for this specific age range on computational thinking. For example, there are some validated questionnaires in English for programming but for the age groups of the last grades of secondary schools and early university years in computer science (see section “[Related Work: Computational Thinking, Gender Difference and Self-Efficacy in K-12](#)”). The same questionnaires use different versions of self-efficacy (see sections “[Self-Efficacy in Gender Difference](#)” and “[Related Work: Computational Thinking, Gender Difference and Self-Efficacy in K-12](#)”) and are often modified, customized, and translated according to the needs of the research context. On other occasions, the items of the instrument to which the students have responded (whether a questionnaire, interview, or other) are not even reported when the research is published but only a general description: this makes it problematic to compare the results. Added to this, these tools do not use all the resources of self-efficacy, as it will be described in the next paragraphs (see section “[Self-Efficacy in Gender Difference](#)”). Very often they are adapted and focused on a specific digital learning environment (like Scratch, Alice, Beebot, and similar) more than on cognitive, emotional, and social aspects of the self-efficacy of programming. Even the translation of the same questionnaire into different languages can lead to alterations in self-efficacy values, linked to different emotional reactions by the students (Aamir et al. 2017).
3. Up to now, the learning of CT has been a niche subject. Usually, it has been limited to laboratory experiences carried out in a few weeks or at most a few months, mainly in noncurricular hours and sometimes in laboratory activities independent from the schools, such as “summer camps” or similar initiatives of which it is not known whether they were followed up or remained isolated moments of study (see section “[Related Work: Computational Thinking, Gender Difference and Self-Efficacy in K-12](#)”).
4. The introduction of CT in K-12 appears to be inserted into the curricular activities of different countries with a notable slowness (Royal Society 2012), due to the fact that some countries are lacking teachers of the discipline. To obtain a complete picture, research must not be limited to the self-efficacy of children without taking into consideration the self-efficacy of their teachers too. The efficacy beliefs of teachers influence their instructional practices and their students’ achievement (Bandura 1997). These considerations demonstrate that

it is problematic and premature to present a complete picture on the issue of gender difference in learning CT in K-12, compared to other school subjects that have long traditions of research (such as writing, mathematics, and the sciences) and where self-efficacy findings are based on annual curricular teachings extending for decades across all grades of school.

Self-Efficacy in Gender Difference

Self-Efficacy: Definition

Self-efficacy, a construct developed by Bandura (1977) within the framework of social cognitive theory, refers to “*people’s judgments of their capabilities to organize and execute courses of action required to attain designated types of performances*” (Bandura 1986, p. 391). Nearly 40 years of research have amply demonstrated that self-efficacy beliefs are related to cognitive, motivational, affective, and behavioral outcomes in a variety of domains (Bandura 1997). In the school setting, self-efficacy refers to the beliefs that students have in their ability to perform required learning tasks. Students with high self-efficacy persevere longer, engage in the search for a deeper meaning in learning tasks, report less anxiety, and have higher results at school (Bandura 1997; Pajares and Schunk 2005). Students’ self-efficacy has been shown to predict the results achieved in various academic areas, such as mathematics, science, and writing (Usher and Pajares 2009; Pajares 2003). Just as self-efficacy predicts students success in specific domains, students’ beliefs influence their ability in self-regulated learning, which indicates how students are able to implement self-regulated strategies in school activities (Zimmerman 2008).

It has been demonstrated that self-efficacy beliefs are correlated with students’ academic motivation, self-concept, goal orientation, performance, and anxiety, as well as attitudes to success and risk of dropout (Caprara et al. 2008; Zimmerman 2008). Given the central role played by personal self-efficacy beliefs as determinants of academic success, much research in education

has begun to focus on the processes by which these beliefs are formed.

Bandura (1997) considers that personal beliefs formed during primary schooling are likely to be the keystone on which subsequent beliefs of effectiveness are built up. However, as Usher and Pajares (2009) point out, while there is much research on self-efficacy beliefs for age groups ranging from 11 to 17 years (Bandura 2006), there are only a few studies that have investigated sources of self-efficacy among students at the primary level, a period in which children are particularly receptive. Much remains to be understood about gender differences for this age group, for which the available data are still insufficient.

Self-Efficacy and Related Concepts

One of the best ways to define self-efficacy is to distinguish it from related concepts with which it can be confused (Bandura 1997; Zimmerman 2000). Self-efficacy does not refer to a perceived skill but to what a person believes they can do with their abilities under certain conditions.

Self-efficacy also does not refer to beliefs about the ability to perform simple and trivial acts but rather to beliefs about the ability to (re) organize one’s abilities in certain changing and challenging situations.

This construct investigates what an individual is able to do and not what he/she would like to do (intention) or what he/she is used to doing (habit). Intentions indicate what he/she will probably do (even if intentions are influenced by a series of factors that also include self-efficacy), while habits are courses of actions already in place and do not, accordingly, represent challenging situations.

Self-efficacy is not self-esteem. Self-esteem concerns what persons believe about themselves and how they feel regarding what they believe about themselves. This construct concerns wider areas of the life of the individual and is influenced by the importance that the determined field of action has in his/her existence. Self-efficacy, on the other hand, is related to a specific domain and to actions aimed at solving a problem. For example, a researcher investigating self-esteem would ask a student “*How good are you in computer*

science”, while one investigating self-efficacy would ask “*How certain are you that you are able to detect the variables of this problem?*” (Zimmerman 2000).

Finally, beliefs of self-efficacy are not expectations of results; Bandura (1997) believes that expectation theorists have isolated commitment as the sole reason for a resulting performance; they concentrate on the amount of effort expended in habitual activities, conceptualizing commitment as neither mutable nor sensitive to challenge. Self-efficacy, on the other hand, directs subjects to make an effort to understand the quality of their performances and in particular the beliefs that lead them to apply themselves in situations that require perseverance.

Self-Efficacy: Multidimensional Concepts

Self-efficacy varies on diverse dimensions that regard beliefs of magnitude, strength, and generality (Bandura 1977).

Magnitude refers to the difficulty of the task. People can vary their level of self-efficacy depending on how much they believe a particular task is easy or difficult for them. This level can also vary depending on the need of people to face challenges, as some may be motivated to engage concretely in a challenging activity, while others avoid difficulties because they do not feel able to face them.

The strength of expectations refers to the effort that a person is able to activate for a long period of time and in the presence of obstacles. It follows that this dimension does apply to the ability to perform a known trivial and occasional activity; it applies rather to whether a person is able to persevere continually over time, even in the presence of difficult conditions. For example: a strong expectation cannot easily be extinguished by negative experiences, while weak expectations may crack at the first hurdles or adversities.

Generality refers to the ability to transfer self-efficacy from one area to another: for example, *from algebra to statistics* (Zimmerman 2000). This dimension takes into account the self-assessment individuals make regarding their self-efficacy in both a wide range of activities and also in restricted areas. Generality also includes the

following subdimensions: the degree of similarity of the tasks, the modalities of expression of the capacities (behavioral, cognitive, and affective), the characteristics of the situations, and the characteristics of the persons to whom particular behaviors are directed.

In the contexts described above, when data on self-efficacy are to be collected, it is important to plan for a specific behavior to be measured in the performing of a precise task, to predict what obstacles might arise to be dealt with through interventions and whether the purpose is to include transfer components or not.

Sources of Self-Efficacy

In general, Bandura (1997) has theorized four sources of self-efficacy that can influence people’s beliefs and have a mediated effect on behavior: performance accomplishments, vicarious experience, verbal persuasion, and emotional arousal. At the educational level, it is important to understand the sources of self-efficacy and to intervene in them, both to identify the needs of the students and to create or improve their expectations of self-efficacy and then allow the students to implement a specific behavior to achieve the desired results.

Performance accomplishments refer to one’s own experiences and to the history of personal behavior or performance achieved. These are also called enactive mastery experiences. They are indicated by Bandura (1997) as the most influential sources of information, when compared with others, since they provide indicators of the beliefs inherent in the abilities possessed by a subject. Bandura (1997) explains that information on self-efficacy derives both from the performance implemented in the context, including the characteristics of the task, and from the self-efficacy beliefs already held.

Successes help to improve self-efficacy beliefs while failures weaken them, especially if they occur before a sense of effectiveness is established, particularly in the stages of cognitive, affective, and social development of the child. However, Bandura (1997) emphasizes that a strong sense of self-efficacy requires learning over time, in order to develop the more sophisticated components of this construct, such as the

sense of resilience, as well as developing knowledge of the rules and strategies necessary to deal with difficulties (Usher and Pajares 2009). For example, it is important to link successes with persevering efforts, if a person wants to avoid discouragement in the face of possible failures.

In this perspective, difficulties are in themselves a learning opportunities, if they are interpreted by the subject (or the subject is guided to recognize them) as moments for transforming their weaknesses into strengths and to develop the ability to control events.

Vicarious experience is the second source of self-efficacy; it is as influential as the first and includes experiences observed by the individuals themselves (Bandura 1997; Usher and Pajares 2009). This resource refers to learning by modeling learning and explains the extensive knowledge that children acquire by observing other people, both in their presence and through the media. This learning is not automatic: what the child learns is influenced by the aspects of observed behavior to which he/she pays attention and his/her ability to interpret and remember. Children's vicarious experiences are based on models that function as organizing principles of their knowledge and behavior, from which they draw conclusions to apply to their own behavior and their own predictors. The more the model (the other person observed and taken as a reference) has the desired characteristics, the more likely it is that the observations will have an impact on the child. Self-efficacy is particularly sensitive to vicarious experiences, especially when children (or adults) are inexperienced or not confident about their abilities (Bandura 1997). The models taken as reference become a source of inspiration against which to measure and self-evaluate one's own abilities. Observers learn knowledge, skills, and coping strategies by understanding how effective models behave (Bandura 1986). Hence, self-efficacy can be influenced and modified by the models observed by the child, who can subsequently transform its own behavior. If the observed models display characteristics such as trust, perseverance, and resilience to difficulties, that can instill a higher sense of effectiveness in comparison with models who show signs of

distrust, self-doubt, and avoidance of difficulty (Zimmerman and Ringle 1981) or that carry out tasks too easily, without ever encountering problems. From gender research, it emerges that both women and men are particularly attentive and susceptible to models whom they believe to be credible and worthy of trust; although, it should be noted, women in the scientific-technological sector complain about the lack in their experience of female models to inspire them (Zeldin and Pajares 2000; Usher and Pajares 2009).

The third source is verbal persuasion. It is a weaker factor than the first two (performance results and vicarious experience) (Usher and Pajares 2009). Verbal persuasion can be defined both as verbal feedback from others and as instructions provided by texts for self-learning activities. Verbal (and social) persuasion is an additional resource for reinforcing an individual's beliefs that he/she possesses the skills to achieve the desired goals. In difficult situations, one is more likely to maintain a good degree of self-efficacy when others express confidence, rather than doubt or discouragement, in the abilities of the subject. However, social persuasion can also cause negative effects, either through negative feedback or by raising unrealistic beliefs about the skills possessed (Bandura 1997).

The fourth and final source of self-efficacy is emotional and physiological experiences. Individuals also estimate their self-efficacy on the basis of somatic information related to emotional and physiological states (Bandura 1997; Usher and Pajares 2009). Stressful or particularly demanding situations can provoke physical and emotional reactions which, if not controlled and elaborated, can be interpreted as signs of vulnerability or dysfunction and thereby influence self-efficacy judgments of one's (in)competence and/or (un)controllability (Benson 1989). For example, it is difficult to avoid perceiving states of tension, nervousness, fatigue, and pain, which are alarm bells of our physical and mental system when under stress, but if these states are interpreted as signs of insecurity or personal incapacity, they may create distortions in the processing of information and result in negative judgments of self-efficacy. Furthermore, self-efficacy is influenced by the way

emotional states are perceived and evaluated. For example, educational interventions can guide students to recognize physical states and emotional excitement and to rework their feelings constructively in order to develop forms of resilience (Bandura 1997). Such interventions can also help students to recognize wrong representations and to modify mistaken cognitive representations and nonfunctional interpretations.

In the school environment, the influence of anxiety on self-efficacy beliefs has been documented, above all, for mathematics, which is a source of common concern for students, especially for girls (Bandura 1997; Usher and Pajares 2009). Studies have amply documented that there is no direct relationship between past experiences and anxiety; this connection necessarily has to go through a low sense of self-efficacy. If the reasons for the failure are attributed to external causes, this will not affect the self-efficacy, and therefore, the levels of anxiety will remain unaffected. On the contrary, if the cause of failure is attributed to personal factors, self-efficacy will suffer and anxiety levels will tend to increase. Since female students are more insecure about their skills in the discipline, they are more likely to set up mechanisms of the second type (Bandura 1997). It follows that as anxiety correlates to poor scholastic performance; this relationship generally vanishes or decreases when one works on the rules and strategies of self-efficacy representation, on dysfunctional thought patterns, and on the processes of interpretation.

Measuring Self-Efficacy: Specific and General

Bandura (1997) distinguishes three levels of self-efficacy measurement: (1) The most specific measurement is the level of one's sense of self-efficacy for a particular performance in the presence of a specified set of conditions. (2) The intermediate measurement level regards the sense of self-efficacy for a category of performance within a particular sphere of activity in the presence of a set of conditions that share common properties. (3) The most general and global measurement level is of convictions of personal effectiveness without specifying the activities or conditions in which they will be employed. In this vein, some

researchers have also worked on the existence of more general self-efficacy beliefs. In this case, these are measures developed on the concept of general self-efficacy, which Judge et al. (1998, p. 170) defines as the personal beliefs that people have of their ability to "perform in a variety of different situations", while Sherer et al. (1982, p. 664) defines it as a suitcase of beliefs [of self-efficacy] that "the individual carries into new situations".

In particular, there are the three scales most used in research, which were designed by Chen et al. (2001), Schwarzer and Jerusalem (1995), and Sherer et al. (1982). These scales have proved to be reasonably good predictors of self-efficacy performance in a wide variety of measurements and in a wide range of fields (educational, clinical, health, and organizational), showing good internal consistency and good test-retest reliability.

Related Work: Computational Thinking, Gender Difference, and Self-Efficacy in K-12

The next section ("[Computational Thinking: A Multifaceted Concept](#)") introduces some definitions of CT to delimitate the field of research that is examined in the following sections, despite the fact that the concept is multifaceted. Section "[Gender Difference in Computational Thinking](#)" is devoted to research on gender differences in CT in K-12, organized according to the elementary and middle school level. With the same organization, section "[Gender Difference in Self-Efficacy in Computational Thinking](#)" focuses on a series of studies that investigated gender differences focused on self-efficacy and how self-efficacy beliefs influences the experiences of children and girls on computational thinking.

Computational Thinking: A Multifaceted Concept

Before proceeding with the presentation of studies concerning gender differences, it is necessary to understand what is meant by CT and the difference with other terms such as "coding" and "programming," sometimes used with different meanings

and sometimes as synonyms. In this work, CT is interpreted as complex thought process (Wing 2006) in which “programming” and “coding” constitute two important aspects. “Programming,” in particular, refers to the analysis of a problem, the design of a solution, and its implementation. “Coding,” on the other hand, represents only the implementation phase of the solution by means of a particular programming language.

The CT definition is still under discussion in the international scientific community (NRC 2010, 2011). Mishra et al. (2013) underline how despite the strong interest of different countries regarding computational thinking, there are still many problems and challenges to be addressed to integrate CT in the school curriculum. The first of these concerns the definition of CT; next it is necessary to understand what are the attributes and the concepts underlying the CT, how to evaluate them, how to teach them to the students, how to train teachers so they can effectively integrate CT in their classes, and finally the types of research that must be done to promote the inclusion of CT at school.

Wing uses the term “computational thinking” as shorthand for “thinking like a computer scientist” (Wing 2006) and, more specifically, the thought processes involved in formulating a problem and the description of its solution in such a way that a person or a machine can effectively carry it out (Wing 2017).

Mishra et al. (2013) do not offer a common definition of CT but propose two perspectives of this concept; at the micro level, CT can be seen as teaching how to program a computer, using specific programming languages; at the macro level, CT can be seen as a set of “ways of thinking”, such as systems thinking, problem-solving, algorithmic thinking, etc.

Soman et al. (2012) highlight how the processes activated in CT concern the decomposition of a problem into smaller and easier subproblems, the recognition of patterns, the definition of abstractions, the choice of the resolver algorithm, the data analysis, and presentation of the work carried out. Wing (2017), in particular, emphasizes abstraction is the most significant process, by means of which even the most complex

problems can be addressed. However, it is important to bear in mind that the Wing’s definition is general and refers to adults, since the cognitive process of abstraction matures around the age of 14.

Fristoe et al. (2011), in a research article with middle school girls related to programming environments, maintains that the age from 11 to 13 years is a key moment in which to involve students (male and female) in programming environments, because most of them have the cognitive ability to engage in abstraction and reflection. In addition, the students are still in the process of exploring their own identity and the girls, in particular, still evaluate positively the activities of designing computer games.

Other researches, based on Brennan and Resnick (2012) model, used in order to analyze students’ performance in terms of computational thinking, underline how for most of them the process of abstraction is not clear.

Brennan and Resnick argue that CT can be evaluated in three ways: CT concepts (concepts used by the programmer, such as the concept of variable, loop, etc.), CT practices (practices used during the programming process), and CT perspectives (students’ understanding of themselves and the technological world around them, including questioning the nature of technology, the reuse of code and the concepts of abstraction and modularization).

As argued by Lye and Koh (2014), the majority of studies that used this framework explored issues related to CT concepts; yet it seems there is a gap in the research related to CT in K-12, especially regarding the dimensions of CT practices and CT perspectives (Grover and Pea 2013), areas that include the most important processes of computational thinking, such as abstraction.

Taking into account that the scientific community has not reached a common agreement on CT yet and that, in the meantime, many research projects relate to different aspects of computational thinking, it follows that research on gender differences, including those on self-efficacy, suffer from the same problems. The next sections move precisely in this direction, presenting the main research results in the field of gender differences

in CT and subsequently, in greater detail, self-efficacy in CT laboratories for primary and middle school students.

Gender Difference in Computational Thinking

Primary School

Several CT studies that especially investigated programming, such as the creation of computer games, motivational aspects, and learning strategies, did not report important differences between males and females. For example, Hsu (2014) in a US research work concerning gender differences in games creation with Scratch, carried out with primary school students, showed how both girls and boys have significantly improved their programming concepts and benefit from programming laboratories. Therefore, there are no gender differences in terms of programming concepts, even if the girls seem to better master the concept of counting loops. Also Vos et al. (2011), in a study conducted with 235 primary school students from the Netherlands, analyzed the difference in intrinsic motivation and deep strategy use by proposing two activities: in one, the children built their own game, while in another, they used games made by others. The research results showed that allowing children (male and female) to build their own games led to significant improvements in intrinsic motivation and deep strategy use compared to the use of games already made by others. In particular, this study found no gender differences in perceived competence, interest, or use of deep learning strategies.

However, other research, which widened the focus of investigation, underline some gender differences, highlighting how girls seem to have a more contextualized view of technology.

Mawson (2010), for example, in a research conducted with children aged 5–10 in New Zealand highlights how girls find it more difficult to define what a technology is than do boys. Girls seem to have a broader and contextualized view of technology and have conflicting views about the value of the same for society. Boys, on the other hand, have a more positive attitude than girls towards technology and its usefulness. Elvstrand et al. (2012) and Hallström et al. (2015), in two

research projects carried out in Sweden with first-year primary school children, which aimed to observe pupils while they built their own games, both with LEGO and poor materials such as ropes, cans, and tubes, observed that girls, when they use technologies to build something, often have a very specific purpose in mind, such as creating an object to be used in everyday life, while boys see the construction process itself as the main purpose of the activity. Research with primary school children conducted in Finland (Virtanen et al. 2015) and in the USA (Brunner et al. 1998) demonstrate that girls are particularly involved in useful and meaningful projects that have connections with everyday life, for example, the construction of useful and decorative artifacts for their homes, while boys appear more experimental and tend to construct objects for their own sake (Hsu 2014). In addition, girls tend to create games contextualized in realistic worlds, while boys prefer to make adventure games in fantastic environments.

Girls' attention to context (attending to the purpose for which they are using a technology and to the usefulness of the task) leads to another difference with boys, related to problem-solving approaches.

Research conducted in the Netherlands by Heemskerk et al. (2009) concerning the use of ICT underlines how females, in addressing a new task, prefer, more than males, clear instructions and collaborative activities, while boys prefer, more than girls, less information about the task, but a certain level of competition. Moreover, females seem to prefer activities that require greater creativity, while males require more dexterity. Also Ching et al. (2000), in a study conducted in the USA that involved students aged 10–12 in developing computer programs noted how boys prefer to address problems and solve them on their own, while girls prefer to be led and participate in more collaborative environments in which they can share with others what they do.

A study conducted by Kowiyah and Mulyawati (2018) with primary school students in Indonesia about the ability to represent in mathematics found a strong use by children of figures and tables. The researchers show that boys get

better results during action planning; in fact, the use of tables and figures was concentrated during the problem-solving planning. The girls, on the other hand, get better results and show more use of tables and images, during the problem-posing phase, that is the phase of problem understanding.

Other research underlines the relation between students' performance and the particular software they use. Joiner et al. (1996), for example, in research conducted in the UK with children aged 10–11 does not find a relationship between boys' favorite software and their performance but a significant connection between the girls' favorite software and their performance.

The above-mentioned research explores gender differences which, extended and deepened, could provide useful information for teachers, who have to design their school activities to involve boys and girls to the same degree.

Middle School

With regard to middle school, research shows greater gender differences than at primary school. Despite the fact that some research, carried out especially in the mathematical field, does not show marked differences between males and females, Perez-Felkner (2014) in a US study with middle school students found that the perception of their scientific abilities decreases in girls aged 13–14 years and above. Perez-Felkner (2014) has shown that girls in the fourth grade are more likely to choose to continue in a scientific path, which they do not consider difficult. This result is reversed in the eighth grade, when 36% of girls say they do not want to continue in scientific studies, compared to 30% of boys; moreover, 56% of girls say that scientific subjects are too difficult, compared to 44% of boys. Other research tends to confirm this gender difference, which seems to start at adolescence and strengthen over the years (Eccles 1987). Sáinz and López-Sáez (2010) in research conducted in Spain involving 550 middle school students aged 12–16 point out that from the last years of middle school, females tend to prefer subjects and fields of study in humanistic and social sciences, despite having better grades in technology than males and the

various initiatives carried out by universities to encourage girls to care about technological studies. Sáinz and Eccles (2012), in a study conducted in Spain on ICT, also find great gender differences in middle school students. Sáinz and Eccles (2012), in particular, underline how these differences are affected by the concepts pupils have of their own computer abilities, as confirmed by other studies, which have shown that students' choices are affected by psychological factors such as hierarchy of interests, ability self-concepts, domain-specific self-efficacy beliefs, and perception of the costs and benefits of being involved in specific activities.

The research world also highlights another difference between males and females in middle school concerning the approach to the study of computational thinking. A study conducted by Werner and Denner (2009), with 126 middle school students in California concerning computer programs development, shows that females, more than males, try to solve problems by collaborating with others. Furthermore, their research shows that girls are more interested in learning CT when there is more emphasis on collaboration during the problem-solving process. The same result is also obtained by Baytak and Land (2011) who, in a study conducted in the USA concerning computer games design, report that the involvement of girls stimulates social interaction and the creation of a community around information technology.

Heemskerk et al. (2009), in a research conducted in the Netherlands concerning the use of ICT, and Fristoe et al. (2011), in a research conducted in the USA with middle school children about the learning environments to use to introduce students to programming, underline that girls seem to prefer educational games and tools that facilitate the cooperation and sharing of what they learn more than competitive environments.

As emphasized in the previous section, it is important that teachers take into account these characteristics of students during the design phase of laboratories on computational thinking. As highlighted by Vekiri (2010), in a research conducted in Greece with middle school students

on value and efficacy beliefs of males and females in information technology, and also supported by studies conducted in other countries, such as (Clarke and Teague 1996) in Australia and (Goode et al. 2006) in the USA, teaching computer science tends to be still teacher-centered and focused on the development of decontextualized technical skills, offering students few opportunities to collaborate and to be involved in exciting, creative, and significant tasks.

Gender Difference in Self-Efficacy in Computational Thinking

The previous section recounted various gender differences that have been revealed by research on computational thinking in K-12. This research concentrates mainly on middle school and is mostly concerned with the lower interest that girls compared with boys have in technical-scientific subjects. This section will investigate this phenomenon with particular attention to students' self-efficacy beliefs, apparently one of the major causes of gender differences in this area.

With regard to primary school, there is little research that investigates gender difference in the sense of self-efficacy related to computational thinking. However, there is research which reveals that from primary school, girls generally tend to have a lower self-efficacy and self-confidence than males in technology, as highlighted in the following studies.

Endepohls-Ulpe et al. (2012) carried out a study aimed at developing innovative pedagogical practices and learning environments which encourage girls to choose courses of studies and professions in the field of natural sciences and technologies. In the first phase of this study, students (boys and girls) who had already undertaken a course of study in a technological field were asked to think about the factors that encouraged or discouraged them in their educational choices. The study involved both engineering and non-engineering course students in Austria (average age 22) and Germany (average age 23). The first factor analyzed was "Intellectually based interest and high self-efficacy in science and technology" in primary school. In relation to this factor, both

males and females who study engineering recalled having been more interested and competent in science and technology than colleagues who did not study engineering. In general, boys valued themselves greater than girls; it seems that an interaction effect is present between gender and field of study; males who do not study engineering remember to have been more interested and competent in science and technology than females who do not study engineering, while this difference is not so high between males and females studying engineering. The findings of the study highlight how girls, in general, remember from their time in primary school a low level of self-efficacy and a lower intellectually and practically based interest in technical-scientific subjects than males. In addition, engineering students, compared to others, report higher self-efficacy and intellectually and practically based interest in technical-scientific subjects, and there do not seem to be major gender differences. These students, compared to those of nonengineering courses, also remember strong support from their fathers for their interest in technology.

Another interesting study is that carried out by Hallström et al. (2015), which aims to investigate how Swedish children aged 3–6 explore and learn technologies in games (children have free access to Lego and other poor materials such as ropes, cans, and tubes) and how their teachers frame these activities in their teaching. The study uses an ethnographic approach and is based on qualitative data collected through video-recorded observations and informal chats with children and teachers. During data analysis, the notes collected were codified and, after repeated readings, the codes were grouped into categories: construction play, purpose of construction, gender differences, self-confidence and teachers' activity. The researchers found no differences among children when they draw and create patterns at the beginning of an activity. However, during the experiment, which is a fairly new situation for children, boys are more active than girls, who distance themselves from the activity. The researchers believe that this result is connected with a lower degree of self-confidence in girls than boys. The

same difference in self-confidence was also noted in other circumstances, for example, when boys had to introduce themselves. In general, boys are more eager to try something new than girls, especially in relation to technology and science. During the construction of a tower with blocks, for instance, which is a nonstereotyped activity perceived as masculine, girls do not feel as involved as boys; indeed, in this situation, they become “helpers” of the boys.

Virtanen et al. (2015) make a similar finding. In fact, in an exploratory study on the differences in motivation between males and females towards technological education in a Finnish primary school, which involved 281 students of the fifth and sixth years, they found that boys had a higher level of self-confidence, more enthusiasm in the lessons, and more fun in learning how to use different tools than did girls.

However, other studies, such as the one conducted by Sinan et al. (2014), demonstrate that gender has no effect on the sense of self-efficacy. In their study, Sinan et al. (2014) aim at determining the science attitudes and the self-efficacy levels of 296 students from three primary schools in Turkey. For data collection, two scales were used: Science Attitude Scale and Generalized Self-Efficacy Scale. The research results showed that gender has no effect on science attitude and self-efficacy; instead, they showed the presence of significant differences between fifth year students and those of the following years, in favor of the latter.

In summary, gender difference in the sense of self-efficacy seems to start in primary school and continue in secondary school, up to university, where girls show less self-efficacy than boys, especially when having had less computer learning experiences. To confirm that, He and Freeman (2010) carried out research that aims to study the mechanisms through which gender influences the development of the general Computer Self-Efficacy (CSE), involving 174 US students aged 17–20 in a basic computer course. CSE is a particular application of Bandura’s more general self-efficacy construct (1977) in the field of computer

science and is commonly used as one’s judgment of his/her capability to use a computer. There is both a general and a more specific version of the CSE: General CSE (GCSE) refers to a person’s judgment of his/her ability to operate across multiple computer application domains; specific CSE refers to the individual’s effectiveness perception in performing specific computer tasks. This study considers that computer skills, current computer experience, and computer anxiety act as the main sources of information for an individual to judge his/her level of GCSE. Another source of information, such as verbal persuasion, is not included in the research model, since its influence in self-efficacy development is considered weak and vulnerable (Bandura 1977). The research results showed how female students had fewer computer skills and less computer experience than males. They also appeared to be more anxious in computer use and have lower levels of GCSE. The researchers argue that computer experiences and computer anxiety have mediated the effect of GCSE and suggest increasing the informatics experiences of girls, in order to help them develop greater security with computers.

There is also research that does not reveal differences in the sense of self-efficacy between males and females in middle school concerning computer science, such as the study conducted by Vekiri (2010). Vekiri involved 301 middle school students in Greece (grade 8 and 9) in order to examine self-efficacy beliefs among males and females in information technology and to inquire into how they perceive parent support and teacher expectations. Research found that perceived teacher expectations are positively associated with students’ beliefs about their computer skills. Unlike other studies, the results of this research did not reveal differences in males’ and females’ self-efficacy and value beliefs in ICT among middle school students. Instead, the study highlighted how their beliefs are differently influenced by parents and teachers. Specifically, perceived teacher expectations are more significant for the effectiveness of girls than boys, while the opposite is true regarding perceived parental support.

These results are confirmed also by de Weerd and Rommes (2012) who investigated the role of teachers in secondary school students' choices regarding science and technology. In particular, they revealed how teachers' attention perceived by females towards them are closely connected to their self-efficacy, a relation that does not exist among males, whose self-efficacy does not seem particularly influenced by teachers' attention.

Conclusion

The previous sections presented several research papers that investigate the role of gender difference in the sense of self-efficacy related to CT in K-12. Most of these papers show that girls, from primary school on up, tend to have lower self-efficacy than boys in technology, even if some investigations exist that state the opposite (see section "[Related Work: Computational Thinking, Gender Difference and Self-Efficacy in K-12](#)").

In general, it can be stated that gender differences in the sense of self-efficacy seem to start in primary school and continue in secondary school and into university. The diminished sense of self-efficacy among girls and women seems to be influenced by a complex set of beliefs about their experiences of CT in scholastic, family, and friendship circles (see section "[Self-Efficacy in Gender Difference](#)"). No comparison was possible among the variety of published research into self-efficacy (see section "[Related Work: Computational Thinking, Gender Difference and Self-Efficacy in K-12](#)"). That is because this work refers to students of different ages and nationalities, while some of it is focused on specific tasks and others look at more general aspects of CT.

In addition, the researchers use different scales to measure self-efficacy, indeed, very often they use questionnaires created ad hoc and validated internally (see section "[Introduction](#)").

To conclude, it is important to underline how research on self-efficacy in CT among K-12 students requires attending to factors that could contribute to producing distortion or even error

effects on analysis and interpretation of results. Pajares (2005) highlights four factors.

1. The first factor refers to achievements and previous practices, internal and external to the school context: if these variables are not checked, gender differences regarding academic beliefs could be "invalidated" (or better, nullified, Pajares 2005).
2. The second factor is the tendency of boys and girls to adopt different approaches when they respond to self-efficacy instruments. It is important to be cautious in reading and interpreting the results, as attention should not be limited to a mere statistical index. The reasons for this lie in the psychological development that characterizes the K-12 phase (but also beyond), which is different for males and females. In fact, adolescence for girls starts between 9 and 11 years while for boys between 11 and 13 years. Specifically, at this stage of life, several studies on girls and boys of the same age show that girls suffer from a decrease in self-efficacy in science (and some other subjects) compared to boys, and this gap increases as they age. Therefore, in interpreting the data, it is important to take into account the differences in development between males and females (mentioned above) and to hypothesize that because girls filter and process research questions more critically, they show a lower sense of security than their male colleagues.
3. The third factor to which to pay attention concerns the differences in average confidence levels reported by males and females. These variations are due to the variables of comparative judgments of self-efficacy based on beliefs not only in relation to the whole class or of the group of participants but also on the basis of the distinct sets of males and females. Therefore, it is important to include questions that take into account comparisons with classmates of the same gender and with the other gender. In this regard, Pajares (2005) points out that the analysis of gender differences, before coming to the conclusion that they actually exist, should know

how, for example, girls evaluate their self-efficacy not only with respect to the whole class group (or the whole group of participants) but also with respect to the separate groups of boys and girls. (This procedure is valid for both older and younger children.) Disaggregating data at this level helps to discriminate and better understand the beliefs of males and females.

4. The fourth factor that can affect gender differences in self-efficacy deals with stereotyped gender beliefs and is differentiated from the actual gender of the subject. The reference is to all those social, cultural, family, personal, and academic variables that can orient convictions about gender. From the Eccles (1987) studies, we learn that stereotypical gender differences seem to emerge and become influential during preadolescence and increase throughout adolescence. This happens first in girls and then in boys, due to the different ages at which they enter into puberty. These changes in the development phases depend on the maturation of the socialization processes, which become more and more sophisticated, as well as comparisons with “the others” (Eccles 1987); it is a period in which the role of gender is intensified, but so also are gender stereotypes held by adolescents. Eccles (1987) shows that there are a series of factors in the cultural milieu, including stereotypes of gender roles, that can play a decisive role in the commitment to certain disciplines compared to others in school and in future choices of university and career. Research shows that the more girls identify themselves in terms of female stereotypes of women’s occupations, the more likely they are to show attitudes of avoidance or rejection for scientific fields. There are studies that demonstrate that the influence of family, culture, and mass media is an important and at times crucial component in gender differences. For example, if parents consider science as a “male domain,” this can lower the motivation and interest of girls, as well as reduce their self-assurance in these areas. Research shows that many girls have an unjustifiably low sense of self-efficacy, despite having achieved tangible

results at school and demonstrated real potential. Even today, this potential cannot be prevented from being wasted. Society continues to lose talent that could contribute to the work, research, and development of the technology and scientific sectors.

Introduction

Women got involved with computer science (CS) literally from the moment of the creation of the scientific discipline and have passionately programmed computers for many decades. As far back as 1843, Ada Lovelace wrote programs on Charles Babbage's mechanical computer. In 1946, six women mathematicians, known also as human “computers” created working programs for the ENIAC computer during the Second World War. In the 1950s, the pioneering generation of CS featured a surprising number of prominent women who led research teams, defined computer languages, and even pioneered the history of CS. One of the first programmers, Grace Murray Hopper, played a key role in creating COBOL and standardizing FORTRAN, even named as the Data Processing Management Association's first “man of the year” in 1971 (Misa 2011).

In the 1960s, women entered the emerging CS profession in unusually big numbers. In 1970s, 22.5% of computer programmers were women

(Ensmenger 2011) while in mid-1980s women earned 37% of all US bachelor degrees in CS, and across these decades, women constituted about the 38% of the US “white-collar” CS workforce (such as systems analysts and software developers). Despite these early successes, in the late-1980s, women stop entering CS in big numbers, and the proportion of women studying CS actually began falling dramatically (Camp 2012).

Since then, the gender gap in CS has raised global concerns that gained more importance with the emerging Information Age. These concerns have motivated excessive research during the last decades, investigating the extent of the underrepresentation of women in CS education and workforce as well as addressing possible key factors affecting women’s participation in CS. The research identified several critical issues emerging from the unequal participation of males and females in CS, the most important of which are: (a) the huge demand that exists for people trained in CS, (b) the need for a diverse workforce to innovate high quality technologies, and (c) the goal of equal opportunity of both genders in the field.

Despite the widespread usage of computer technologies, only a small, unrepresentative sample of the population is involved in creating new technologies. In the USA, the overall need for computer scientists has severely outstripped the number of graduates entering the workforce, and it is estimated that only 17% of the 3.5 million CS-related jobs in the USA by 2026 will be filled by the US CS bachelor’s degree recipients. The great need of computer scientists is a reality for the EU as well. In particular, it is expected that 889,000 CS positions will be vacant in 2020 (Hüsing et al. 2013). However, women and other underrepresented groups are likely to bring great potential for filling these gaps both in the USA and the EU as gender diversity in CS workforce seems to improve productivity, creativity, innovation, and competitiveness. CS is a field created by innovative thinkers whose products and systems have become critical and have affected the daily lives of a broad section of the general population. Ideally, computer technologies should be developed by a population as diverse as its users. Increasing

the diversity of viewpoints in CS may help to ensure the design of new technologies that meet the needs of the diverse society.

However, the gender gap is not only an issue for CS but also for the rest Science, Technology, Engineering, and Math (STEM) fields. Gender differences in CS+STEM fields are reflected in the presence of females in CS+STEM tertiary education as well as males’ and females’ performance and preferences within these fields. Placing emphasis upon any gender differences in CS tertiary education, the aim of the present entry is to: (a) outline the gender representation in CS departments (depts), in terms of students, graduates, and faculty members, reporting results from a systematic analysis of data from a whole decade concerning all CS depts of an entire country (Greece) as well as comparisons of gender representation within CS+STEM fields, (b) to disclose the barriers that deter females from participating in CS, (c) to present performance issues in CS with an emphasis on the common stereotypes about females’ lack of abilities in CS, along with specific results from a study, conducted in Greece, regarding the curriculum of a CS dept so as to dispel the “myth” of gender differences in terms of performance, and finally (d) to discuss the effect of gender on course preferences in CS education supported by specific results emerged from a case study conducted in a specific CS dept in Greece.

Gender Representation in Computer Science Departments

CS has evolved from the discipline of math, but as electronic computers became accessible to the public, CS has started to be recognized as a valid discipline on its own. In the early 1960s, CS departments started to split themselves out from math departments and the first actual bachelor’s degree in computer science being awarded at Purdue in 1962. In fact, CS field grew rapidly from an esoteric field of study in the mid-1960s to a popular major by the mid-1980s, changing more rapidly than most STEM disciplines (Misa 2011).

Despite this fact, the number of females in CS has been falling since the mid-1980s, whereas

women continued to increase their representation in most of STEM disciplines. Specifically, the percentage of CS undergraduate degrees awarded to women in the USA had been decreasing since the mid-1980s from a high of 37.1% to a low of 17.8% in 2012 with a consistent descending trend (Camp 2012). This descending trend is unique in CS, as the proportion of undergraduate degrees awarded to women in all disciplines has increased the last decades reaching to a high of 57% in the USA in 2012, and the percentage of undergraduate degrees awarded to women in biological/life sciences, engineering, and physical sciences increased by 26.5%, 40.6%, and 47.8%, respectively (Camp 2012). More recent data show that while 57% of 2016 bachelor’s degree recipients in the USA were women, just 19% of CS bachelor’s degrees were awarded to females.

A clearer picture of the representation of women in CS in the USA – built by combining data sets from the National Science Foundation in the USA and longitudinal surveys – reveals that there are “*distinctive trajectories and dynamics*” at the undergraduate level compared to the graduate level (Hayes 2011). While women’s participation in the graduate level (master’s and doctoral degrees) is still low, there is a slight increase across the decades. It is at the undergraduate level, since the “turning point” in the mid-1980, in which the proportion of women earning CS degrees constantly declines. Compared to other STEM disciplines in which the proportion of women has been steadily increased, CS seems to be a field of extremes, being both the fastest growing and declining during different time periods concerning the representation of women (Hayes 2011).

The trend of female participation in the CS workforce follows a pattern similar to that in undergraduate CS education, especially for “white-collar” professions. The percentage of CS occupations in the US workforce held by women has been declining since 1991, when it reached a high of 36%, dropping to 26% in 2017. Despite the shrinking representation of females in CS undergraduate studies and workforce, the proportion of women at higher ranks, doctorates and faculty, have continued to grow overall (Hayes 2011).

To further clarify the gender representation picture drawn above, a specific example related to undergraduates’ (freshmen and graduates of bachelor’s degrees) and graduates’ (graduates of Master’s degrees and PhDs) representation in every Greek CS and Computer Engineering dept is presented below. In addition, an example illustrating results closely related to gender representation of faculty members in all Greek CS and Computer Engineering depts is also reported (Berdousis and Kordaki 2016).

Example of Gender Representation of Undergraduates and Graduates in CS Departments: The Greek Case

In this study, data regarding undergraduates and graduates from all Greek CS depts and Computer Engineering schools (“CS” – 14 CS University departments and 8 Electrical and Computer Engineering Schools) for a whole decade, 2002/2012, were quantitatively analyzed and compared to other STEM depts, namely: Biological Sciences and Environment (“Bio/Env”), Physical Sciences (“Phys”), Mathematics and Statistics (“Math”), and Engineering (“Eng”).

Table 1 demonstrates the total numbers (N) of male and female freshmen, graduates of undergraduate studies, graduates of master’s degrees and PhDs during the decade 2002–2012. The mean percentage of the female (%F) freshmen, graduates of undergraduate studies, graduates of master’s degrees and PhD are also presented in respect to all Greek Universities and Engineering Schools (“Overall”) and Greek CS depts and Computer Engineering schools (“CS”).

Gender Differences in Computer Science Departments, Table 1 Gender representation of students and graduates in Greek tertiary education 2002–2012: overall and CS

Undergraduate / graduate	Overall		CS	
	N	% F	N	% F
Freshmen	410,085	60.53	32,247	26.50
Graduates	313,332	64.33	17,798	29.54
Master	69,170	57.37	5933	34.45
PhD	15,666	38.78	2152	14.96

It seems that, “Overall,” more than 60% of the freshmen were females, nearly 65% of the bachelor degrees were awarded to women, whereas, almost 58% and 39% of master degrees and PhDs were earned by females, respectively.

As for “CS,” during the decade under study, about one out of four freshmen were females, while nearly 30% of the undergraduate degrees and almost 35% of the master degrees were awarded to females. The proportion of females who earned PhDs is even lower, down to approximately 15%. It is promising though that, despite the downward trend regarding the percentage of female freshmen throughout the decade, the percentage of female graduates is, on average, higher than the percentage of female freshmen while the percentage of female graduates of master’s degrees is higher than the respective number of female graduates of undergraduate studies (see Fig. 1). The upward trend in the percentages of female graduates of master’s degree programs in Greek CS depts over the last 7 years of the decade under study is another promising point. It verifies that a considerable percentage of women pursue and achieve a CS master’s degree after graduation. Additionally, as the decade progressed there was an observable increase in female graduates of PhDs. Eventually, the percentage of master’s degrees and PhDs

awarded to females appears a clear upward trend through the decade.

Comparing the presence of females in Greek CS depts with other STEM depts of the decade under study, in terms of freshmen, graduates, masters, and PhDs, it seems undoubtedly that females are worst represented in CS depts in all the aforementioned levels of study (see Fig. 2). Females in “Bio/Env” depts clearly outnumber males in every level of study, while in “Phys” depts, female are almost as many as males in terms of freshmen, and graduates of both undergraduate and graduate studies. Regarding “Math” depts, females approach the numbers of males, apart from PhD degrees where just one out of four graduates are females. Even in “Eng” depts, females constitute constantly over 30% of the freshmen and the graduates from undergraduate and graduate studies, leaving behind females in CS depts.

Example of Gender Representation of Faculty Members in CS Depts: The Greek Case

The presence of female faculty members in CS depts can play a crucial role in female-student retention in the field, as they demonstrate the presence, the participation, and the continuing prospects of women in CS. The positive role of a female role model in the retention of females in

Gender Differences in Computer Science Departments,

Fig. 1 Female students in CS depts in Greece: 2002–2012

Gender Differences in Computer Science Departments, Fig. 2 Females in CS+STEM depts in Greece: 2002–2012

CS highlights the need to investigate the presence of the female faculty, who could act as mentors/role models in CS depts. Taking CS depts in Greece as an example, data from the Hellenic Statistical Authority were exploited and a quantitative research was conducted to examine the gender representation of faculty members of all ranks (professors, associate professors, assistant professors, and lecturers) of CS+STEM depts in Greek tertiary education during the decade 2003–2013.

Table 2 presents the average number of faculty for each one of the four ranks in the aforementioned decade, and the percentage of females (%F), regarding all Greek Universities and Engineering Schools (“Overall”), as well as CS depts and Computer Engineering schools (“CS”).

Regarding “Overall,” among the four ranks, females were better represented in the position of lecturers, followed by assistant professors, associate professors, and professors. This appears to be the case for CS depts as well. It appears that female faculty in CS depts was better represented as we move down towards the lower ranks.

Focusing on the CS depts and the fluctuation of the percentage of females in each of the four

Gender Differences in Computer Science Departments, Table 2 Gender representation of faculty members in Greek Tertiary Education, 2003–2013: overall and CS

Faculty members	Overall		CS	
	Average number of the decade	% F	Average number of the decade	% F
Professors	2551	18.15	224	6.34
Associate professors	2050	28.52	113	12.54
Assistant professors	2589	33.57	140	14.20
Lecturers	1691	39.38	76	17.21

ranks throughout the decade, noteworthy trends are revealed (Fig. 3). The percentage of female professors appears to be the lowest among ranks for each year of the decade, varying from almost 3% to 8%, with a slight upward trend in the first years of the decade. The percentage of female associate professors in CS depts varied from about 8% to 16%, following a downward trend

Gender Differences in Computer Science Departments, Fig. 3 Female faculty members in CS depts in Greece: 2003–2013

throughout the decade. The percentage of female assistant professors varied from 12% to 18%, decreasing in the first 2 years of the decade, fluctuated for the following 3 years and remained at around 15% in the last 4 years of the decade. The downward trend in the first years of the decade appears to be true for female lecturers as well. Their percentage varied from almost 11% to 21%, with a clear upward trend in the last years of the decade. Bearing in mind the upward trend regarding the percentage of PhD degrees awarded to females, the presence of females in academia is probably an expected advancement.

Comparing the female representation, regarding faculty members, in CS depts with the rest of the STEM fields, it is apparent that the percentages of female faculty in CS depts were the lowest among all STEM disciplines in every rank (Fig. 4). Females were better represented, in every rank, in “Bio/Env” departments, while their percentages in “Phys” depts were the second highest. Interestingly, females in CS+STEM fields seem to be better represented as we move down the ranks. Yet, the upward trends regarding the presence of females in academia, even though it mainly concerns lectures, along with the ascending trend

in PhD degrees awarded to females, seem to be encouraging and promising for a better representation of females in the future.

Barriers That Deter Females from Participating in Computer Science

An explanation for female underrepresentation in CS education given by Abbate (2011) assumes that, as college students flocked to CS in the mid-1980s, depts tried to cut down the numbers to a manageable size. Thus, many depts instituted entry requirements that favored candidates with prior computer experience, discouraging those students who had less experience or confidence. As a result, fewer women than men had been admitted to CS. The gendered effects of these changes were probably unintentional, but true. Hayes (2011) provides another explanation, arguing that as the discipline of CS became established and known to the general public during the 1970s and 1980s, unappealing stereotypes of computer scientists as “computer nerds” and “hackers” also became well-known in the general consciousness. The increasing prevalence of these stereotypes from the 1980s through the present day may have contributed to a decline in the proportion of

Gender Differences in Computer Science Departments, Fig. 4 Female faculty members in Greek CS+STEM depts: 2003–2013

women choosing CS. These stereotypes were probably unappealing to both men and women but disproportionately to women. What is more, as CS professionalized, CS programs were settled in different depts, such as mathematics, physics, and electrical engineering and accommodated in a variety of colleges ranging from liberal arts to physical sciences and engineering. Progressively, these programs became independent CS depts, mainly located in engineering colleges. In this way, CS started out with a wide variety of disciplinary cultural influences, and it has gradually moved closer to a culture of the “male-dominant” engineering.

The reasons for the underrepresentation of women in CS have been an issue of interest for many decades. Research, over time, has identified several key social and structural factors that influence females’ participation in CS, often deterring them from choosing future CS education or careers in CS (Gürer and Camp 2002; Barker and Aspray 2006; Ashcraft et al. 2012). Females’ perceptions, interest, confidence, attitudes, and career decisions are shaped by the larger environment they learn about the field of CS preventing them from being able to make a truly free choice. In that sense, education, family and teacher

support, computing experience, and stereotypes seem to be crucial factors.

Regarding education, irrelevant curriculum with no connection to real life, teaching practices that discourage collaboration and teachers with (un)conscious bias about girls’ abilities, and the culture of the field may deter girls, even boys, from pursuing CS. The uncomfortable, unwelcome environment in a CS class dominated by boys reinforces the loss of girls’ interest. Families, also, can play a significant role in girls’ and boys’ decision about studying CS. The parental support and encouragement have a decidedly powerful impact on girls’ choices, while the early exposure to both computers and computing at home as well as the kind of computing experience seems to be key factors. Another obstacle seems to be the lack of female role models in CS. It has been proved that the existence of females in the field – teachers, faculty, and colleagues – can inspire women, improve their self-efficacy, and reverse negative stereotypes as they can realize, through real-life examples that they can pursue, persist and succeed in CS. The perceived similarity with successful women in the field, and the feeling that they “fit in” could be a crucial factor in pursuing CS (Gürer and Camp 2002).

Most recent studies also contend that one novel and powerful social factor that may perpetuate the underrepresentation of women in CS is the *stereotypes* about the culture of the field, which in some cases act as “educational gatekeepers,” discouraging females from entering CS (Cheryan et al. 2015). The image of a computer scientist is one of a genius male computer hacker who spends a great deal of time alone on the computer, has an inadequate social life, and enjoys hobbies involving science fiction. These stereotypes are dominant in our society and students tend to espouse them. Those girls, even boys, therefore, who feel out of that culture, abandon the idea of pursuing CS.

Gender Differences in Performance in Computer Science Education

Beyond the stereotypes about the culture of CS, females face negative stereotypes about their abilities, making them feel like they do not fit well in the CS field. These negative stereotypes are based on some socially constructed “myths” about gender differences in cognitive skills and academic ability. These “myths” are not real in a scientific and empirical sense regarding actual measures of ability and intelligence, but they are real, as they have real social implications; they constitute obstacles discouraging females. Even though there are no gender differences in cognitive skills and ability, people still believe in and behave in response to the belief of such gender differences, and consequently, a large gender disparity persists in higher education and careers in the CS+STEM fields.

Evidence from the STEM fields indicates that there are no significant differences in performance between males and females, with males to perform slightly better on the construct of science and have more self-efficacy (Kiran and Sungur 2012). The fact that the gender gap in measurements of STEM ability and achievements has narrowed and nearly disappeared has been mentioned since 1990 (Mickelson 1989). The ability and intelligence of males and females in science subjects showed little to no difference (Mickelson 1989), while, especially in math performance, gender differences were small, and in some

cases, females outperformed males but only by a negligible amount (Hyde et al. 2008). Later studies emphasized on the performance of males and females in STEM in high school, and specifically, on the tools that school uses to measure science achievements: grades and test scores. Even though males and females were similar in achievement, females had higher final grades in STEM while males had higher test scores (Britner 2008). In a review of 25 years of evidence, Jacobs (2005) maintained that differences in grades is generally weak and concluded that females have achieved increasing success in STEM courses, closing the gender gap, while a later study showed that no significant gender differences were found on five science academic outcomes (Matthews et al. 2009). Some evidence from CS also suggests that male and female students seem to perform equally well in CS courses (Ilias and Kordaki 2006).

Nevertheless, when different subject domains are taken into consideration, females perform better than males on the social aspects of science factors, while males tend to perform better than females on the constructs of science factors (Kiran and Sungur 2012). Upon closer inspection within the STEM fields, differences emerge in terms of which discipline males and females follow in education and career (Amelink 2009).

There is some evidence demonstrating that performance is closely related to the domain-specific self-competence, self-efficacy beliefs and motivation, which are affected by the above-mentioned negative stereotypes (Jacobs et al. 2002). Actually, those students who believe that they have the ability to accomplish a particular task perform better and are more motivated to select increasingly challenging tasks (Ibid). In fact, expectancies of success (such as self-efficacy) are critical issues in educational and career choices. Thus, computer self-efficacy predicts involvement with computers and intention to take CS courses (Sáinz and Eccles 2012). The more appropriate a subject is considered for males, the lower is females’ self-efficacy (Correll 2004). Females tend to have low self-efficacy and believe they have little natural ability in male-dominated domains, including mathematics,

engineering, and CS. In particular, females' self-efficacy is low when compared to their actual abilities, skills, or performance (Correll 2004). Beyer (2014) found evidence for actual gender differences in computer self-efficacy, stereotypes, interests, and values. Increasing females' computing self-efficacy would positively affect their representation in CS. Regarding especially CS, research suggests that computer self-efficacy is also influenced by computer experience (He and Freeman 2010) and previous performance (Correll 2004).

In order to provide a deeper understanding about the gender gap in the performance in CS education, a study investigating gender differences in terms of performance in the entire curriculum of a CS department is presented below.

Example of Gender Differences in Performance: The Case of a Greek CS Dept

In this study, data from a Greek CS dept were analyzed in order to explore gender differences in graduates' performance in CS courses (Berdousis and Kordaki 2019). Specifically, 89 degrees covering a 6-year period of graduation at the Department of Computer Science and Technology (DCS&T), University of Peloponnese, Greece, were studied. This study has taken into consideration the degrees of all graduate students who enrolled from 2002 to 2008. The number of male graduates was 69 (77,53%), and the number of female graduates was 20 (22,47%). These percentages of male and female graduates are in line with a relevant research about the representative percentages of CS graduates from CS depts in Greece (Kordaki and Berdousis 2017).

According to the curriculum of DCS&T, in that academic period, students had to enroll in 21 compulsory courses as well as in 25 electives and successfully fulfill the appropriate requirements in order to award a degree. According to the curriculum, courses were classified into three divisions, namely: "Theoretical Computer Science" (TCS), "Software Systems" (SS), and "Computer Technology and Computer Systems" (CTCS). TCS had 3 compulsory and 10 elective theoretical CS courses, SS had 8 compulsory

and 29 elective software engineering courses, and CTCS had 3 compulsory and 15 elective hardware-oriented courses. There were also 2 groups of courses: "Math and Physics" (M&P) consisted by 7 compulsory courses related to Mathematics and Physics, and "General Education" (GE) that included 21 elective courses regarding social, ethical, law, and humanities issues. The data regarding the 89 graduates were collected from the official records of the DCS&T without any reference to the personal data of the graduates apart from their gender. Those data referred to the gender of each graduate, the courses that she/he had passed along with her/his grades. For each one of the 100 available compulsory/elective courses, mean grades and standard deviation values for males and females were calculated and independent sample t-tests were conducted to compare the mean grades of male and female graduates.

The analysis revealed few statistically significant differences in performance, and specifically in ten CS courses, between male and female graduates. It seems that males performed better than females in seven courses and females better than males in three courses (Table 3). Interestingly, males performed significantly better than females in four courses from the SS division, as well as in two compulsory Math courses and one course from GE division. Females, on the other hand, performed significantly better in Human-Computer Interaction, and one elective from the CTCS and GE divisions correspondingly. In that sense, the findings from this CS dept in Greece are in line with relevant studies in CS+STEM (Ding et al. 2006; Ilias and Kordaki 2006; Kiran and Sungur 2012; Alkhadrawi 2015), which support that there are no major differences in performance between males and females, and that, when different domains (in this case, divisions) are taken into account, males tend to perform better than females on the constructs of science factors, in case of CS; math and programming, whereas females perform better than males in the social aspects and the use of computer technology, such as interfaces between people and computers (Human-Computer Interaction).

Gender Differences in Computer Science Departments, Table 3 Gender differences in graduates' performance

Statistically significant differences between males' and females' performance in CS courses (per division)								
Division	Courses	Group statistics				Independent samples test – T test for equality of means

Gender Differences in Preferences in Computer Science Education

To this point, it seems that females do not participate in CS+STEM education as much as males, yet when they do, they perform equally well. Beyond the different preferences of females in terms of specific subject domains, differences in course preferences within each subject domain are also evident. Course selections within STEM fields reveal certain persistent differences in preferences regarding STEM (Alkhadrawi 2015). Even when the overall number of males and females in science majors is nearly equal, the specific field within science still differs significantly: males select high-level mathematics, engineering, CS, and physical sciences in higher numbers, while more females choose biology and

chemistry (Amelink 2009). It appears that males attach a higher value and utility to math and have higher self-concept in math, engaging in the math field more frequently than females (Van de Gaer et al. 2008).

As for the reasons which shape these preferences, it seems that self-efficacy in CS+STEM is an important one which affects not only students' choice of courses but also their decision to select a major in these fields (Beyer 2014). Additional factors, such as interest in CS, computer confidence, conscientiousness, and openness to experiences have been acknowledged as significant predictors of taking CS courses (Beyer 2014).

Focusing solely on CS, a study investigating the course choices of male and female students from the entire curriculum of a CS department

would uncover gender differences in terms of course preferences. The following second phase of the example of the Greek CS dept will discuss these preferences of CS courses of male and female graduates.

Example of Gender Differences in Preferences: The Case of a Greek CS Dept

Along with the differences in the performance of males and females in CS courses, the study of the degrees from the DCS&T in Greece revealed gender differences in course preferences (Berdousis and Kordaki 2019). Table 4 depicts the CS elective courses from which it is evident that there are statistically significant differences in course preferences between males and females.

The data analysis revealed that males selected at a higher percentage, compared to females, two elective courses related to computer architecture from the CTCS division (Computer organization), and advanced topics of Software Systems from the SS division (Advanced User Interfaces, VR). GE electives were not popular among male students, compared to females. The above-mentioned course selections of male students enrich the findings of relevant studies in STEM fields which support that males take engineering and advanced CS courses in higher percentages compared to females (Bussey and Bandura 1999; Amelink 2009).

On the contrary, females selected at statistically significantly higher percentages than males eight electives: three of them are related to the Theoretical Computer Science division (Computational Geometry, Fractals, and Cryptography) as well as three courses related to humanities and social sciences from the GE division (pedagogy, sociology, and cognitive science). These selections of females enhance the findings of other relevant studies in CS which explain that females prefer theoretical computer science issues as well as the social aspects of CS and the solutions of community problems over computing for the sake of computing (Margolis et al. 2000). They seek to interact with people rather than things, desire to be helpful to others or society, and pursue to combine career and family (Beyer 2014) in a “balanced” life with multiple roles and goals (Eccles 2007).

It is a fact that there are differences in the selection of CS courses between male and female students in CS education. These differences in preferences may reflect stereotypical views about the role of males and females in CS, different personality characteristics and self-efficacy beliefs (Beyer 2014), as well as diverse values and interests of males and females. Males prefer courses focusing on the core of CS, while females prefer courses oriented towards theoretical issues as well as seeking to

Gender Differences in Computer Science Departments, Table 4 Gender differences in graduates’ preferences

Statistically significant differences in the course preferences of male and female graduates						
Division	Courses	Graduates who selected the course (%)		Chi-square test

be useful to others pursuing interaction with people (Beyer and Haller 2006).

Summary

Over the last years, gender gap in CS+STEM education is an issue that has raised global concerns. Female representation in CS+STEM secondary and higher education and gender differences in performance and preferences within these fields are research topics that merit attention. Focusing on CS higher education, the present entry attempted to portrait gender differences in CS depts by: (a) outlying the gender representation in CS depts, (b) discussing the obstacles that deter females from participating in CS, (c) deliberating performance issues in CS, and (d) analyzing the effect of gender on students' preferences in CS depts. Regarding students, graduates, and faculty representation in CS depts, the results from a systematic analysis of data from a whole decade concerning all CS depts of Greece were also presented, whereas, differences in performance and preferences were also discussed on the basis of a study conducted in Greece concerning the whole curriculum of a CS dept.

In spite of the remarkable presence of females in CS the first years of its establishment as a scientific field, the number of females in CS has been falling since the mid-1980s, while women continued to increase their representation in most of STEM disciplines. Especially in CS higher education, it seems that females are constantly underrepresented in undergraduate and graduate studies, with a downward trend regarding freshmen. It is promising though that, there has been an upward trend in the percentage of the master degrees and PhDs' awarded to females the last years. Despite this encouraging trend in graduate studies, it was clear that the percentages of females in CS depts regarding undergraduate and graduate studies were the lowest compared to other STEM fields. The recruitment and the retention of females in CS+STEM depts, among other factors, seem to be influenced by the presence of female faculty members in these depts. Unfortunately, females faculty members

in CS+STEM depts are the minority, and, as the aforementioned study in Greece indicated, among the four ranks (professors, associate professors, assistant professors and lecturers), females are better represented in the lowest position, that of lecturers. Things for CS depts appear to be even worse, as the percentages of female faculty in those depts were the lowest among all STEM disciplines in every rank. Taking the above into consideration, it seems that females are clearly underrepresented in CS depts. The reasons for this underrepresentation are complex and multilayered. Females' perceptions, interest, confidence, attitudes, and career decisions are formed by the larger environment they learn about the field of CS. Especially, negative stereotypes about the culture of the field prevent females from entering CS as they fell out of the culture, while stereotypes about their capabilities in CS create a "myth" about gender differences in cognitive skills and academic ability, enlarging the gender disparity in higher education. Reinforcing the results of relevant research in STEM fields, the study conducted in Greece, regarding students' performance in the CS courses of the whole curriculum of a CS dept showed that there were not major differences in performance between males and females, and that, when different domains are taken into account, males tend to perform better than females in math and programming, and females better than males in courses related to interfaces between people and computers. This study also discovered gender differences in course selection within CS domain, revealing that while males take engineering and advanced CS courses in higher percentages, females prefer courses oriented towards theoretical issues as well as courses related to the social aspects of CS.

Definition

There are innumerable definitions that have been proposed regarding the concept of ethics throughout the ages. One of the simplest and most general, while at the same time most illuminating, defines ethics as a set of moral principles that drive the behavior of a person. By implication of this definition, ethics are not fixed, since the moral principles of both individuals and societies can be changing, even volatile. There is a strong philosophical and ethical tradition in Western countries coming from the ancient Greek schools

of thought. This tradition, although important in the West, cannot eclipse other philosophical and ethical traditions, for example, the Chinese and Indian traditions; and since no one can be considered superior to another, it is necessary to construct an ethical paradigm based on the diverse cultural currents and historical traditions of the world. Said paradigm would have as its main advantage its integrating character, although one cannot ignore the complexity inherent in the attempt to reach a universally accepted agreement on what behavior is ethical or not (Gammack and Goulding 1999).

Introduction

Information technologies (IT) are instruments that make it possible to streamline the processes of capturing, organizing, combining, using, storing, and disseminating information. As such, they use a material – information – which, although intangible, has a relevance that can be significant because of its influence on goods and people through the decisions made using it. Since the large-scale development of computers and information technologies in general, an important role has been given to technological factors and those related to the development of methodologies that help ensure the success of information systems. This vision was logical due to the high cost of technological infrastructures and the personnel in charge, which constituted a strong condition for those responsible for information systems and technologies. Over the years, the great development that information technology has experienced has led to the economic factor being moved increasingly toward the background and other factors, previously barely considered, gaining prominence (Cederberg and Valenza 2012). Some of these factors are related to the human sphere and have to do with personal, social, and ethical issues. In the following sections, considerations will be made on these issues and how they can affect the work of educational management teams in terms of their decisions regarding the IT infrastructure in their charge.

Ethics and IT

It is not easy to find a balance between the protection of information of a personal nature and the right of the rest of society to know information that may be of public interest (privacy vs. freedom of information). This dilemma becomes even more difficult considering that we are immersed in an information-intensive society of a multicultural nature, which is, therefore, continuously growing in complexity (Hagen 2009). It could be argued that the ethical aspects present in the management of educational IT, since the field of ethics is dynamic and continuously evolving, integrating different perspectives and cultures, are nothing but a mirror of the times, marked by a continuous cultural and economic globalization.

Having the ability to collect, process, store, and use information gives a form of power to educational managers. For this reason, educational managers must be aware that this power has an associated level of responsibility and that its objective is to use the available information to offer a set of services that allows the stakeholders of the education system (students, teachers, administrators, parents, and society in general) to work more efficiently or improves the quality of their lives.

At this point, it is pertinent to distinguish between aspects related to the assurance over privacy of information, for which procedures have been developed under laws in many countries, and others that have to do with decisions of an ethical nature. The first group can include questions such as who should have access and to what information; how to protect individual privacy; what should be considered as information belonging to the education center; what information to offer to other educational entities and to society in general; or how long to maintain the storage of electronic records, to give some examples. For this purpose, laws such as the EU directive on the processing of personal data (European Union 1995) and the US Health Insurance Portability and Accountability Act (1996) have been promulgated. On the other hand, other aspects also intervene, fundamentally of a social and

human nature, on which it is more difficult to legislate, but which have great importance due to their influence on people and societies. In order to cope this broad spectrum of situations, some codes of ethics have been developed by numerous prestigious institutions. These codes do not only focus on aspects related to the privacy of information, which, as has been mentioned, is an issue widely accounted for in numerous national laws. The following can be mentioned in this group: (i) Ethics Code of the American Society for Information Science, (ii) American Library Association, and (iii) International Center for Information Ethics (ICIE).

Technology has an impact on society as a catalyst for innovation. IT, which is possibly the fastest developing form of technology in the history of mankind, has impacted all societies across the globe. This impact, which is not only economic but also of social type, is not alien to any kind of ethical interpretation. At the educational field, at times, it is difficult to elucidate at precisely what moment the managerial teams of education centers should intervene to avoid any damaging effects on individuals and on society, as a whole, that could result from an unethical use of IT at education centers.

Effect of IT on Work and Work Strategies

IT, from its inception, has had a double influence on the generation of employment. The need to provide organizations with competent people to implement and maintain complex computer systems, both in terms of hardware and software, has generated a requirement for specialized personnel and, from the beginning, the impulse to create new studies, both vocational and superior, aimed at training a new type of professional. It can be said that the rise of studies related directly or indirectly to IT (information technology, electronics, telecommunications, materials physics, etc.) has influenced and, at the same time, has been influenced by the development of IT. These are professional careers that either did not exist or existed with relatively little importance (as in the case of telecommunications engineering) just

a century ago. Today, such occupations are considered a fundamental part of the professional sphere and constitute a significant number of the courses on offer both in terms of vocational training and in higher education. The individual trained in these professions continues to enjoy favorable expectations of professional integration, given that the new manifestations of IT (social networks, artificial intelligence, cybernetics) also demand new professionals, and it is highly likely that the demand for this type of professional will continue to increase for the foreseeable future (Mardis et al. 2017).

However, parallel to the development of IT and its favorable implications for job creation, it has also helped to give rise to, on the contrary, a phenomenon of job loss (Trusson and Woods 2017). This is due to the increasing automatization of tasks that can be carried out more efficiently by automated systems. A job loss also may occur in those occupations that IT can support in such a way that a smaller volume of human labor is necessary. This is the case, for example, for workers on assembly lines, accountants, and in areas of the administrative field, among many others. This double implication of IT has been debated for a long time, and experience seems to point to the need for continuous adaptation of professionals to the new environments developed by IT, through training and professional retraining. The most pessimistic consider this phenomenon a steady and inevitable replacement of people by machines, while the most optimistic consider it an opportunity for people to do more creative and stimulating work, leaving repetitive, monotonous and mundane work for the machines.

In the field of education, where IT has also burst in through the door, there has not been a significant, negative effect on the level of employment for human beings. For educational managers, traditionally, the priority has been to use IT as a tool for improving the teaching-learning process, enhancing the teacher's role in the classroom rather than usurping it, which has meant that, in this particular area at least, there has been no substitution of human beings for machines. On the other hand, given that the administration of education centers, except the most complex ones, such as universities, has

not traditionally included a strong human component for the accomplishment of administrative tasks, there has not been a dramatic change in the level of employment in these positions either at schools or education centers in general. The administration staff of these centers, from the smallest to the largest, use IT as a support tool, although it is still necessary for them to perform functions analogous to those that were done before the inclusion of the IT in processes pertaining to the administrative duties of education centers. However, educational managers should consider in their future agenda the possibility that IT will significantly affect the number of teachers in their centers. The development of teaching materials by companies and organizations specializing in education and massive online training systems, among others, may lead to the choice of using these resources, compelling teachers to acquire a lesser role in the formative process and reducing their numbers overall.

Another aspect related to the possible negative influence of IT in the workplace may spring from its tendency to break down the boundaries between home and work-life. The availability of electronic devices that, via different types of networks, allow contact with the office, both by voice and by data, is increasingly resulting in the home becoming an extension of the workplace. This subtracts from time that belongs to the individual and that should be regarded as personal. Often, managers make use of mobile phones, e-mail, or messaging apps to contact employees or colleagues regarding work issues during non-office hours. On the other hand, the workload, insofar as meeting objectives and deadlines, can be so demanding that it gives rise to the need to continue working at home, creating the paradox that it is the employee who shoulders the expense of contracting, and paying for the services of, service providers who ensure the quick access to the network that makes the home a more efficient workplace.

In the field of education, it is relatively easy for this circumstance to occur due to the fractional nature of the work. Of the professional group with the greatest presence in education, teachers, it is usual for a large portion of their activities to be carried out outside of the workplace, for

example, preparation of classes, correction of tests and exams, preparation of teaching materials, etc. Educational managers may encounter the counter-productive situation that even if they intend to avoid practices that lead to teachers working outside of their place of employment or work schedule, they actually promote this situation with their decisions. The creation of virtual electronic work spaces (online repositories of teaching materials, tracking and management of student activity systems, online administrative systems, etc.) can lead to the continued use of IT from the homes of the teachers. In this case, it is difficult to establish any kind of recommendation. The incorporation of this type of electronic virtual environment has become a practical necessity at all levels of education and trying to prevent or reduce its use outside of the hours or place of work could impede one of its main advantages, which is its ubiquity and the possibility of access from any place and at any time. In any case, like practically all ethical aspects related to IT, it should constitute an element of collective reflection on the part of the staff of education centers. In this way, if it is necessary to develop some kind of ethical code in this regard, it should be the result of collective reflection and commitment.

Environmental Considerations

The environment poses a question that has been incorporated relatively recently into the set of social and ethical variables related to the use of IT. Concern for the environment has meant that aspects which, in the past, went unnoticed are taken into account, such as the energy consumption of electronic devices, the life cycle that has ultimately led to the manufacture of each device with its environmental cost, and, finally, the influence on the environment once devices are discarded and become waste materials. The first of the issues is related to the consumption of electricity that keeps the IT infrastructure in operation, both in terms of the equipment itself and the facilities in which they are used (light, air conditioners, etc.). This issue must be addressed by educational management teams in an active way, providing facilities with systems that ensure

the effective shutdown of equipment and utilities when not being used, as well as promoting the awareness of users regarding energy expenditure. In this sense, it could be very useful to inform users about the link between the savings in electricity with a lower level of the emission of CO₂ and other greenhouse gases (Bekaroo et al. 2012).

Another important environmental aspect is the knowledge of the manufacturing life cycle of the electronic device. The manufacturing life cycle reflects the environmental cost of developing a particular device. The life cycle, in the case of computers, quantify the use of minerals, plastics obtained from fossil fuels, the consumption of manufacturing facilities, the transport of raw materials and manufactured products, etc. All these inputs are summed up to obtain a value that indicates, either in the form of spent energy or generation of polluting substances, the negative effect that the manufacture of electronic components has on the environment. The environmental costs could be reflected in a “green label,” which would complement the information regarding the sale price of the product and which, along with the price, serves as a guide to making purchasing decisions. In the case of education centers, which usually carry out purchases of computers and other electronic equipment in bulk, it could contribute greatly toward environmental awareness if all stakeholders were informed about the ecological footprint left by the manufacturing life cycle of devices so that an appropriate purchasing policy could then be followed. This policy would not grant the highest purchase priority to the price or to other variables, such as the availability of technical support services, but to a new, environmentally sensitive variable. Certainly, this policy could imply extra economic cost in the purchase of equipment, although it could be justified before the education authorities for the environmental benefits that it would entail. In addition, acting as pioneers with this type of initiative and, above all, communicating it to other stakeholders may send a powerful message that could be copied and replicated by the families of the students in their purchases of electronic devices.

Related to the environment is the issue of outdated or obsolete electronic equipment becoming waste. Concerns are often raised over the

lack of environmental responsibility that sees electronic waste products ending up being deposited along with regular household rubbish in landfill sites. This irresponsible action is detrimental because electronic devices can include mineral components that are harmful to the environment (mercury, lead, etc.), so these must either be deposited at an approved recycling center or else selective collection of waste must be carried out that ensures its shipment to the appropriate centers for dealing with these materials and substances. Certainly, at the level of the educational center, the responsibility of its management teams ends when the discarded equipment is deposited in an approved center for recycling or selective collection, but it should not be forgotten that there should be some form of assurance by the competent authorities that the recycling facilities comply with the parameters established for this type of center (Agarwal and Nath 2011). It has been detected that, in the past, some of these companies have diverted waste to developing countries, where they are abandoned without any recycling process occurring. In this sense, an initiative of the educational management could be to prolong the working life of these devices. Sometimes, a plan to update equipment, based mainly on increasing the capacity of some of the components of the motherboards of computers (RAM, processors) or their hard drives, is enough to prolong for a significant time the use of computers, depending on their intended use at the educational center. On other occasions, when they have definitively reached the end of their life span according to their purpose within the educational center, their usefulness can be extended by transferring them to institutions or organizations whose users require less computing power and can take advantage of them for other uses.

Health and IT

Concern over health has brought with it an interest in working conditions due to the circumstances in which people interact with the physical elements that surround them, which have been designed precisely to help carry out their

work. Working for a long time with physical and technological devices and instruments can adversely affect health. This detrimental effect on health can be translated into the occurrence of illnesses and diseases that, in the end, mean a reduction in the effectiveness and efficiency of the worker. Therefore, it is neither beneficial to the worker nor to the organization in which the work is carried out. In identifying the negative effects on health and on the productivity in general, there has been growing concern for the improvement of the conditions of interaction between individuals and the devices they use, leading to the development of a scientific discipline called ergonomics. The goal of ergonomics is to understand the interactions between humans and the physical elements that surround them, based on theories, development of work methods, and designs aimed at optimizing health and improving results at work. IT, being another form of technology, can lead to injuries and health problems caused by prolonged use. For this reason, those responsible for the management of IT infrastructure must take this matter into consideration in order to ensure the health of staff (Ahmed and Shaukat 2018).

Specifically, the continued use of IT can lead to physical ailments such as headaches, blurred vision, backaches, fatigue, eyestrain, wrist and finger pain, and repetitive stress injuries (Nicolakakis et al. 2017; Andersen et al. 2011). Based on the ergonomic proposals that have been developed to reduce the likelihood of the manifestation of these ailments, educational managers must promote healthy habits as part of the work routine. It is recommended to receive advice from healthcare institutions, as well as from the educational administration itself about the location and disposition of physical equipment and optimal working conditions (light, ventilation, correct positions to take up at the computer or while using other devices, etc.). These recommendations must be communicated to the user so that they are aware of the importance of following a pattern of healthy behavior regarding the use of electronic devices, and so they adopt all those measures that, in the end, will result in their own good health.

There is another, more subtle consequence of IT use that can affect health, which is hard to warn of and difficult to avoid, known as “technostress.” It is a state induced by heavy use of electronic devices that can generate impatience, frustration and a special kind of sensitivity, and even hostility, toward other people. The possible root cause of this phenomenon lies in the exposure to long working days in computing-intensive environments (Jensen et al. 2002). Subjects, in these situations, end up themselves acting like mere computers, with terse, emotionless responses and an absence of human warmth. Quite commonly, this state of mind manifests in outbursts of anger directed at co-workers when they are, for example, slow to provide answers, or at the electronic devices themselves when they do not function efficiently, among other behaviors. Other nonphysical harmful manifestations that also affect the mental health of people are, for example, the stress and anxiety related to the desire to control technology but the inability to do so, resulting from the continuous development and commercialization of new versions of computers, new operating systems, applications, forms of interaction with technology, etc. One of the most damaging consequences of this stress and anxiety is so-called burnout syndrome, whose most visible symptoms are permanent exhaustion and lack of interest in work. In a similar vein, Internet addiction can be cited, which, through online roles, virtual reality and access to massive amounts of information can generate a feeling of stress at not having enough time to access or assimilate large amounts of information, as well as discomfort or depression when, on the contrary, it is not possible to be connected to the network. The cited manifestations are normally outside the scope of responsibility of educational management teams since they are individual emotional behaviors. However, the incorporation of procedures in the corporate code of ethics of the school, which facilitate the self-identification of addictions or asocial behaviors, can be of great help as a first step for individuals to be aware of the problem and, individually or with assistance, develop skills to overcome stress and anger.

Equitable Access to Individuals

Guaranteeing equal access to information and IT resources is a key issue in trying to ensure that social inequalities do not occur. In this section, we can mention the economic differences that can lead to significant portions of the population being unable to access technology and more specifically the Internet (Gremigni 2018). This situation is known as the “digital divide” and occurs both between continents and countries and within the countries, regions, and communities themselves. This difference can mean in the long term that, in the educational field, there are differences between the level of access and use of IT infrastructure for students, which can condition their professional and social future. This issue corresponds, above all, to political decision-makers in the field of education, although the managers of education centers must be alert to the problem in order to prevent, to the best of their abilities, this type of situation from arising within their sphere of influence. Within this section, it is especially important to guarantee access to technology for groups with disabilities. These groups require access to assistive technologies that enable them to overcome their disabilities and place themselves on equal terms with the rest of the student body. Technological developments have allowed for significant changes regarding this matter. Thus, for example, voice input devices, eye tracking systems, Braille keyboards, etc. have contributed greatly toward reducing the digital divide between students with and without disabilities. Educational managers must ensure the availability of the resources that enable these groups to access information and IT infrastructure on equal terms. It is not only a measure based on an economic condition; it requires a high level of commitment of the part of management teams so that, beyond the mere acquisition of electronic equipment, their effective use is facilitated.

The feminist perspective is another factor that has made its appearance in the field of IT use, although in recent times it seems that the debate regarding the different capacities and motivations related to gender has decreased in intensity. The issue has its origin in numerous studies that

showed a lower level of interest by female students in the use of IT and a lower self-perception of capacity to use it than that shown by males. This situation created some alarm because, if confirmed, it would mean that half of the population could not be easily incorporated into working environments, current and future, based on heavy use of IT. Such a situation would generate a digital divide between the sexes whose long-term economic and social implications could be very negative. However, numerous recent studies point to the fact that it is more a problem of self-perception and self-demand with respect to the use of IT than due to a lower level of competence (Johnson 2012). In this sense, it is an important task on the part of educational managers to ensure that no type of attitude persists that discourages women at any stage of the educational process from attaining the same level of IT proficiency as their male counterparts or, most importantly, encourages a female inferiority complex regarding IT use. If necessary, educational managers should insist that teachers do not accept any difference between male and female students in terms of their interactions with IT systems (Vitores and Gil-Juárez 2016).

Actions to Be Taken by Educational Managers

The typical size of education centers is not on the scale of large corporations or governmental centers, where the volume of employees with access to the IT infrastructure makes it necessary to have a corporate code of ethics in relation to IT. However, the small size, comparatively speaking, of schools should not be a pretext for not developing a specific set of ethical standards that guide the use of IT and handling of information in general. This code could be part of a broader one which would include any deontological or ethical consideration related code of conduct to be followed by all stakeholders. An ethical code of conduct in relation to information and IT should, at the very least, include the following dimensions:

Responsibility and control over information and IT infrastructure. A single person should be designated to be in charge of all information

systems and technologies, as well as manage information. It would be their responsibility to ensure the individual rights of all stakeholders of the education center, the rights of privacy protection, the quality of information systems, and quality of life (e.g., ergonomics, job design, health of employees, etc.).

Rights and obligations over information. The limits of privacy should be established in terms of the use of certain applications (e.g., e-mail) and of the information that the organization has about the various parties, especially the students due to their particular vulnerability.

Summary

The continuous development of IT has meant important changes in the human and social relationships of the people who use it. Undoubtedly, IT has had positive implications that have contributed to improving people's lives. However, other implications have been negative, affecting, among other things, behaviors, relationships, and even the health of IT users. These harmful side effects of IT use are subject to analysis in an effort to discover their causes and the ways in which they can be alleviated. The most common response to the ongoing social and human challenges concerning IT has been the development of codes of ethics regarding the use of information and IT infrastructure. These codes are continually updated according to feedback regarding new challenges that arise and with the experience gained over time. In the field of education, information and IT management also pose ethical challenges. The experience accumulated in other sectors of activity can serve as a reference for actions to be carried out that minimize the negative effects of IT on the various groups that participate in the education system. Educational managers must be aware of these negative effects and address them, leading the development of ethical codes within the education centers for which they are responsible. The success of these codes of ethics depends on the degree of involvement of the management and the motivation that they can muster to achieve their assimilation by all the groups involved.

ICT-Based Inclusive Education

Verónica Marín-Díaz
Faculty of Education, University of Cordova,
Cordova, Spain

Introduction

A discourse about information and communication technologies (ICT)-based education should start with the understanding that, as defined by Gallego (Gallego and Rodríguez 2007, p. 108), “the inclusion movement seeks to construct a new school in which the individual differences are viewed as values and not as problems, and where every member shapes an authentic educational community with a strong sense of belonging.” It should be recalled that for permanent learning to be achieved, it should be initiated by the reflection and the critical thinking of the agents involved, and should concern the relationship between theory and practice, thereby promoting creative learning.

Inclusive education, in general, seeks the active addition of every student in academic as well as social or professional life, and this is the reason why, since the celebration of the Declaration of Salamanca (1994), everyone is

urged to search and eliminate every type of inequality.

As pointed out by Ainscow (2012, p. 40), inclusive education is characterized by aspects such as “a) it worries about every child and youth at school; b) it also emphasizes the presence, participation and academic results; c) inclusion and exclusion are closely related, so that inclusion implies the active fight against exclusion; and d) inclusion is an endless process.” Starting with these aspects, policies can be linked with the resources made available by twenty-first century society to all of its members, meaning that inclusion should be thought of from a digital perspective.

Nevertheless, although this may seem easy, as ICT forms a part of the daily life of most people today, this has contributed to the appearance of two lines of work: on the one hand, the training of teachers on the inclusive addition of ICT into classrooms, and on the other hand, the digital divide. Both of these lead us to discuss e-inclusion and e-exclusion.

E-Inclusion

The introduction of the first computers in education centers resulted in a revolution and a broadening of the shapes and forms of teaching, education and training, as well as learning and our incorporation to active life (Marín and Reche 2011). Thus, a high-quality inclusive education is advocated for, understood to be a basic right and not only as the duty or obligation of politicians, educators, or social agents, as related to the production of transformations that will have an effect in all the facets of a human being.

The inclusion-ICT combination should combine their approaches as a synergy, as a complete e-inclusion that fosters teaching and learning processes that exceed the mere training on the use of a digital resource. Thus, the role of ICT in this pairing should be taken into account from the start. As pointed out by Echataia (2017), the main pillars of inclusive education are, on the one hand, collaborative work, and on the other, networked work, and in this scenario, the

technologies should become a fundamental element for the active and full addition of everyone into society.

Taking into account what has been pointed out by Trujillo and Hinojo (2010, pp. 67–68), the role that the technologies will play in e-inclusion will revolve around aspects such as the following:

1. Potential development of metacognitive processes
2. To increase the ability to develop common collaborative work projects based on an innovative attitude, positioning and philosophy of action
3. To develop cross-cutting themes such as inclusion, interculturalism, constructivism, and quality and innovation
4. To produce educational content based on multimodal creation
5. To irradiate the curriculum with design, development, and innovation with web 2.0 tools
6. To train for the later application on the dynamics of development of the classroom in an efficient manner and based on high quality projects
7. To develop digital competencies and technological literacy in parallel as a result of a programmed structure of teacher's training
8. To establish work networks that last throughout time
9. To develop motivational aspects that promote a person's equilibrium, conditioning him or her towards active participation and commitment with the network created
10. To educate for permanent training as a principle of innovative and constant search in the quest for the attainment of equilibrium
11. To commit to the care of the organization based on values and norms created by the network
12. To evaluate the collaborative work environments as the start and turning point for the knowledge and recognition of individuality
13. To recognize the training on method adaptation required by the teachers on the use of these tools

14. To broaden the work and learn beyond the classroom, school, university or center; or in plainer terms, beyond a specific curriculum and programmed content

Studies such as the one by Ozkan (2015) show that the use of the ICT promotes a great number of learning possibilities, which can and should be transferred to spheres of inclusiveness. They can then become a fundamental element to enable access of everyone into the technological world, resulting in the overcoming of the digital divide, also known as e-exclusion. This last term has brought to the fore the concept of e-inclusion, given that it has brought to light the lack of specific policies that promote it, exceeding the integrative view of the tendencies previously to the boom experienced by ICT, and which are still being experienced.

As a result, it is necessary to train, develop, and achieve a digital or ICT competence that includes “abilities such as the management of information, conflict resolution, creativity, critical thinking, efficient communication, collaboration, work in teams and self-directed learning” (Sunkel 2012, p. 30). Therefore, e-inclusion needs to be discussed. On the other hand, it should not be forgotten that the bringing together and introduction of inclusive education to ICT implies, in the words of Zappata et al. (2011, p. 20), “a process of appropriation of the tool and knowledge, and the construction of concepts that tend to incorporate material and digital resources such as flexible, adaptable and cross-cutting contents.” Within it, social advances, the possibilities of choosing, the availability of resources, the training, the interest, the attractiveness of the interface among other aspects, will imply that they are incorporated into inclusive environments.

Why E-Inclusion Should be Discussed

It is necessary to be conscious that the incorporation of ICT into the education sphere from a perspective of inclusiveness implies the thinking not only about what it is to do, but also why and how.

Answering these questions is not an easy task, as there are many answers to be taken into

account. Thus, there are education professionals who are keen on a participative model, related to collaborative and cooperative work within which inclusion becomes a great referent, and others who, even though they believe that participation is important, do not conceive or think about inclusive participation. Given this duality, an intention can be to provide an answer to these questions from a perspective of digital inclusion.

Why should ICT be incorporated into the practice of inclusive education? Initially, the answer will be to develop or to achieve an improvement in learning and to endow the subject with a greater range of possibilities for participating in life in modern society. Given that this society is digital, it will be necessary to gain digital competence to any level, but also to become digitally literate.

At present, the concept of inclusive education should be linked to the concept of technology uses, given that if the integrative vision of it has been exceeded, it is time to broaden horizons to see where it is possible to go in the search for e-inclusion. This needs to be done from an organizational and cultural perspective that promotes pedagogic innovation, and that facilitates access to new communication processes created by ICT. Ultimately, what is sought with their use, is to break the barriers that impede having a high quality education, and this is found within what has been defined as *Understood: for Learning and Attention Issues* (UDA) (<https://www.understood.org/en>). The principles that underpin the UDA are: representation; action and expression; and participation. The first refers to the possibility of presenting the contents in various formats that are accessible to all; the second indicates that the materials or resources should become accessible for all the students for their interaction; and lastly, it invites the teachers or educators to incentivize the motivation and the interest for using new resources. But for the UDA to be truly effective, it is necessary for an accessible pedagogy movement which supports it, to rest on the curricular development that clearly identifies the learning barriers that the students could have in order to effectively act against them.

Why should ICT be incorporated into inclusive educational practice? The answer could be

concise: its ease of access (Marín and Sampedro 2018), although it implies that teachers must broaden their dedication, for example, by reworking classroom methodology, by redefining it or redesigning it, and it also implies that their participation becomes more creative (Bennett et al. 2012).

Just as Trujillo and Hinojo (2010, p. 63) discuss, it could be considered that digital tools have “opened new scenarios, new ways, different alternatives for participation and relationships, new structures.” In this manner, digital inclusion or e-inclusion could be associated with the creation of new forms of participation by people in society.

According to Luna (2013, as cited in Romero et al. 2018, p. 89), ICT in the sphere of inclusiveness can be classified according to 7 criteria:

- The aim of their use is educational, simulator of independent life, entertainment, accessibility, mobility, and as a communication media.
- The cost of acquisition: high cost, average cost, low cost, and free.
- Medium of access: buying, personalized creation, free download, and online.
- Types of materials offered: interactive resources, resources for printing, and resources for design.
- Type of technology: software, hardware, switch, simulators, virtual reality, and augmented reality.
- Type of media used: videos, audio, images, and animations.
- Type of disability: motor, visual, hearing, intellectual, attention deficit disorder with or without hyperactivity (ADDH), autism, and other development disorders.

These elements will result in teachers needing to specify in which sphere to place themselves for their selection, although other aspects should be taken into account also, such as the availability of economic, geographical, and training resources.

And lastly, how can ICT be incorporated into the practice of inclusive education? Even though diverse forms of incorporating digital tools into the act of inclusion will be discussed later in

this entry, the initial response oscillates around visualizing something, that is, an NGO, an association, a project, bringing attention about a circumstance that demands attention from society, besides wanting to introduce an initiative. The manner or form that can be used for incorporating digital tools into the act of inclusion will begin, as already pointed out, from a vision that is far removed from integration, and based on a vision that proclaims collaboration, cooperation, the action in its broadest sense. For this, it will be important for educators to be trained on their use, as current students are already prepared, as indicated by Silva and Rodriguez (2018).

Training of Teachers in E-Inclusion

The training of teachers has been, is, and will be a constant feature in the education policies in every country. Independently of the training system, everyone in the area of inclusion seeks the same objective: the participation, training, and incorporation of all to have an active life. However, for those wishes and lines of work which the regulations of each state sustain, it is necessary that the variables (the teachers) on which the design and development of inclusive methodologies fall, are trained for this.

Conducting inclusive didactic strategies based on ICT entails that teachers use these resources in a broader sense than the mere instrumental, which implies changing the sense of the verb from a “could do” to a “will do.”

The training that should be given to teachers who will later incorporate the ICT into their classroom practice from a perspective of inclusiveness, starting from a series of aspects such as: learning how to use the ICT as a communication instrument belonging to all and for all; seeing them as an element that amplifies their abilities and competences; using them as an instrument of psycho-pedagogic evaluation; and as an element of entertainment that facilitates the acquisition of knowledge and learning.

It is teacher training centers that need to promote training on the use of ICT from the viewpoint of inclusion, in the broadest sense of the word. Their activities should be supported by previous studies that detect real needs, either

expressed or not, by teachers. Starting from this, the next step would be to design diverse training methods (seminars, courses, training days, etc.) according to the realities of the classroom. The format can be questioned, as a great number of variables must be taken into account (geographical location of the center, availability of the material/infrastructure and economic resources, previous training or lack thereof, physical spaces for the training—in person or virtually, availability of the teachers themselves, who demands the training, and for participation).

The main basis on which the inclusive digital training of the teachers, and on which it should be balanced, is the assumption of a tolerant spirit, based on respect and cohabiting, that assumes the principles of equality of opportunities and democracy for all. This is how curricular sustainability that is needed at this time will be achieved.

Educational Digital Divide or E-Exclusion

The addition of ICT in the life of people has generally resulted in what is now called the “digital divide” or “e-exclusion.” If the digital divide is understood as the lack of possibilities for access to digital resources that facilitate or promote the access to information, education or resources, it is possible to see that it encompasses many kinds of human actions, as this concept implies that other situations of inequality could be produced by it (e.g., the economic impossibility for accessing resources and access difficulty due to geographical limitations, lack of training, type of connection for accessing the resources available on the Web, age, and gender). It should be understood that “digital divide” is a broad and divergent term that provokes at the same time new scenarios for action for inclusive education per se.

In the area of education, discussing it entails that specific moments in the process of learning where it is necessary to conduct individual training events need to be carried out. However, a digital divide or e-exclusion implies that even if ICT resources are being employed in classrooms, these may not be accessible to all the students, breaking away from the principle of equality that promotes inclusive education. The heterogeneity when determining the causes that promote or

provoke the e-exclusion of people in general and students in particular has consequences throughout life, given that as a function of the starting issue that provokes this situation, it will be more difficult or easier to overcome these barriers.

Initially, e-exclusion (digital divide) has a first trigger, which is no other than the economic situation of each community, family, and individual. It is when this is improved, when diverse types of divides begin to disappear. As a result, the development of economic policies designed from a perspective of inclusiveness would then allow access to digital resources to be universal.

The need for education on the use and consumption of different digital devices (tablet, smartphone, computers, and video game consoles) should be considered, and availability of resources should not be negatively affected.

Educational scenarios need to be constructed by the users and the teachers; therefore, the overcoming of e-exclusion is found in two domains. On the one hand, teachers themselves, as already pointed out, need to incorporate ICT into their daily practice of educating as a function of their training, their feeling towards them and their availability, and on the other hand, politicians and education theorists, who are responsible for the management of budgets, which will determine the actions of the former. This last group has a responsibility for not perpetuating systems of social inequality that directly provoke educational inequality.

Web Tools for Inclusion

Bennett et al. (2012) point to the speed with which the Web 2.0 has grown, which has promoted new opportunities, not only for creating, but also for sharing and interacting with other individuals. The latter aspect has been solidified by the different tools that have grown under its umbrella, such as video games, blogs, wikis, photograph and video repositories, or social networks (see Table 1), although as indicated by Maloney (2007), many of them were not born out of an educational or inclusive vision.

ICT-Based Inclusive Education, Table 1 Classification of some Web 2.0 tools according to their type and function

Type	Function	Tools
Communication	For sharing ideas and information	Blogs Audio blogs Video blogs Instant messaging Podcasts Webcams
Collaboration	To work with other people for a specific objective, in a shared work space	Editing and writing Virtual and practical communications Wikis
Documenting	To gather or present evidence of experiences, production, lines of thought throughout time, and so on	Blogs Video blogs Electronic portfolios
Creation	To create something new that can be viewed and/or used by others	Hybrid web applications Virtual communities of practice Virtual worlds of learning
Interaction	To exchange information, ideas, resources, and materials	Learning objects Social markers Virtual communities of practice Virtual worlds of learning

Note: Relationships of Web 2.0 tools according to their classification (Marín and Sampedro 2018, p.403)

This classification will always be in continuous evolution and growth, given that the nature of digital tools is to evolve. The horizon that the Internet leaves open for the creation of new resources should not be ignored.

Social Networks and Web Pages. Are they Inclusive?

The vertiginous development of the Internet in the last decade has resulted in a profound change in the manner of seeing, understanding, and feeling, and about people's places in the world. The Web is the largest window to the world that twenty-first

century man can stare out through, or imagine. Its growth has resulted in changes of social, educational, political and economic perspectives, which, according to Uzunboyly et al. (2011), are linked to three processes: the increase of scientific knowledge; the development of digital culture; and the diversification of teaching modalities. As observed, the three statements come from a positive view of the Web, where the greatest tendency is to share and interact among equals (Schneckenberg et al. 2011; Bennett et al. 2012).

As stated by Prensky (2010), the moment has come when people's contribution to the Web is more important than what they can receive from it, so it is important to incorporate them to the universe of inclusiveness. The rise of the Internet has also brought about the proliferation of a great number of digital resources/tools that can be used in diverse modalities and for diverse objectives.

This philosophy, together with its social side, is the pillar on which the Internet rests. And it is from this social perspective, where the social networks come from, as a catalyzing element of the human impulses and creator of relationships, where it could be said that it has truly meant more than a technological revolution, to one of social character, bringing with it new ways of being creators and apprentices (Holcomb and Beal 2010), in a continuous process of intellectual, social, and emotional growth.

The development of social networks is based on the theory of six degrees of separation which originated with Frigyes Karinthy (1930), experimented and developed by Milgram (1967) and defined as such by Watts in 2003 in his work *Six degrees: The science of a connected age*. Social networks as such were not born with an educational objective, but on the contrary, they complied with a human desire to be connected and informed. It is starting from spaces such as MySpace, Facebook, Instagram, Snapchat, and WhatsApp—iterations of *SixDegrees*—the first social network that was created in 1997 and laid to rest in 2001, that social networks have become popular in academic environments.

Taking into account the classification by Marín and Sampedro (2018) (see Table 1), it can be

observed that social networks are defined as a unifying element of many other categories, so that they can be understood as serving as a loud-speaker that makes latent the different social realities of the present.

Thus, it can be argued that we should delve into the possible uses for inclusiveness that could be provided by them, starting with the basis from which social networks were born: to meet a communication need, the need to belong to an all-inclusive group, to understand, know, and be up-to-date with what is occurring nearby or far from the environment we find ourselves in. This need is intrinsic to humans, for better or worse, from the moment we are born.

Therefore, the main advantages of social networks would be the possibility to share passions, feelings, hobbies, events, knowledge, information, resources, and materials; to contribute to the growth of collective consciousness; to create cooperation groups, and so on. Trujillo et al. (2015, p. 289) state that “the collaborative social networks represent a great opportunity for promoting active learning, shared experiences, commitment of the teachers and students, etc.,” so practically every organization now has a profile in some social network. But, are they relevant? Or has the time arrived when the social network market in this area has become saturated?

There are as many profiles in Facebook, as in Instagram, or associations, education NGOs, social organizations in the world. All of them have in common that they all show what each of them is doing—the activities, projects, workshops, courses, conferences, publications, in their field of work. Thus, this is how the Facebook pages of Save the Children and the Red Cross is calling for funds and informing about diverse situations of insecurity (see Figs. 1 and 2).

The web pages have become a platform for presenting what the NGOs, associations, groups, and education centers have been doing. Thus, the web page of the Association of Cabildos Indígenas del Norte del Cauca-Colombia (<https://nasaacin.org/>) provides a voice to a collective that does not tend to move far from the frontiers of their own country or continent (see Fig. 3).

ICT-Based Inclusive Education, Fig. 1 Save the children social network, Facebook sites

ICT-Based Inclusive Education, Fig. 2 Cruz Roja (Red Cross) and Médicos Sin Fronteras (Doctors Without Borders) Facebook sites

ICT-Based Inclusive Education, Fig. 3 Web page of the Asociación de Cabildos Indígenas del Norte del Cauca Colombia. (Source: <https://nasaacin.org/>)

Already in Spain, a large number of such pages can be found. For example, the association SETEM Andalusia (Spain) (<http://www.setem.org/site/es/andalucia/>), and more specifically its office in Cordoba, present Cordoba society in general and society in particular, with the actions they are conducting at present through its blog (see Fig. 4).

However, although they can be a great catalyzing element of information and presentation of the projects that are being developed, they also present a great handicap to many people. Many of the web pages that are linked to these projects are not maintained through time, even though they still deal with a relevant topic and a broad group of possible followers.

In this sense, it is possible to see that the web page of the EMATIC project (video of the project on YouTube: <https://www.youtube.com/watch?v=Zzv59tbOH9I>) seeks to address this issue (see Fig. 5), from which one is invited to download an application for the learning of mathematics with ICT, even though it is focused toward students with specific education needs (<http://videm.es/ematic/>). This project was born in 2011, but it has not been updated.

On the other hand, the Erasmus+ PRETTi project (<http://www.pretti.info/en>), with the collaboration of

the University of Cordoba, while not emphasizing the importance of ICT for easing inclusive education, the social networks and the web page are used to present it (see Fig. 6). As observed, it is another perspective of the use of digital resources for inclusion. This project also created a page on a social network: <https://www.facebook.com/Project.PRETTi> (see Fig. 7).

In the area of ERASMUS+ projects, the *Project: Adaptive Personalized System for Creating Expression Tools in Social Inclusion of Learners with Verbal Communication Disabilities – TESI* (<http://tesi.dipseil.net/>) also follows the format of the previously mentioned project.

Augmented Reality at the Service of Inclusion

In the Horizon report for Higher Education of 2012 (Durall et al. 2012), a discussion was started on the active surge of a series of technologies, catalogued as emergent, that were entering the education sphere without halt. Four years later, these technologies, although still defined as emergent, had already become a reality. Among these, the type of technology that has become increasingly used is Augmented Reality (henceforth referred to as AR).

Augmented reality was born under the auspices of virtual reality (henceforth referred to as

“Nankameanuka, imia amutanmak nankanestsui. Iña enente iña yacharije ukuknaka nekeñawe” “Lo que empieza, no siempre acaba. El corazón y la memoria saben guardarlo” (Lengua Shuar)

En esta entrada tengo que atinar muy bien, tengo que poner “mucho carne en el asador” y aprovechar para hablarlos de mis gentes. Pero eso sí, voy a ser fiel a la pretensión que tenía con base al mes de noviembre.

El pasado 25 de noviembre se celebró el día mundial contra la Violencia de Género y, como no, ahí estaba yo, metida en la trinchera.

Cuando llegué de Lima, de forma fortuita me invitaron a una reunión donde se hablaría de aquellas actividades que se realizarían desde la Municipalidad de Atalaya; y digo de forma fortuita, porque la circular la recibí mi compañera Edith, que sabiendo mi gran interés en aspectos relacionados con el género, no dudó ni un solo instante en avisarme de tal acontecimiento: ¡Marina, ahí tienes “chamba” de la tuya!

No podría explicaros cómo me siento cuando hablamos de lucha, cuando hablamos de derechos y cuando nuestra arma no es un “machete”, sino nuestra propia voz, las voces que queremos escuchar.

Aunque la realidad sea diferente y el machismo se exprese de otras formas, he considerado muy oportuno implicarme y comprometerme con las mujeres de Atalaya y de forma muy especial con mis niñas de NOPOKI. Entonces, al igual que la señora Mercedes se remangaba para asar el “pollo cangas”, yo me remangué para desmontar todos esos mitos que existen entorno a las construcciones de pareja a través del amor romántico; en eliminar todo tipo de violencia y en utilizar un discurso adecuado para derribar las opresiones a través de la crítica, el análisis y la reflexión. Es bastante gracioso ver sus caras cuando les digo que Cenicienta, en realidad, no quiere compromisos y, además, no come perdices porque es vegetariana. No os voy a negar que en un primer momento

ICT-Based Inclusive Education, Fig. 5 EMatic portal

VR), as it was considered to be a step forward from it. Although here the focus will be placed on AR, what will be presented is paired with the indirect use of VR, because “when comparing

virtual reality and augmented reality, it is found that their differences comes from the fact that they promote formulas of interaction between the subjects and the real world that are completely

ICT-Based Inclusive Education, Fig. 6 PRETTi project Facebook page

ICT-Based Inclusive Education, Fig. 7 Pretti Project Web portal

different. Thus, while virtual reality places one in a completely non-existent world (virtual) that completely substitutes the real one, AR adds a new plane of vision that is different from one’s view of the real world, adding complementary information through the overlapping with virtual

3D objects” (Villalustre and Del Moral 2016, pp. 31–32).

As for AR, the main objective is none other than to bring closer to reality whatever the students learn in class, with the aim of improving their academic performance. There are different

levels of AR, and according to some authors, these are as follows:

Level 0: Hyperlinks to the physical world (a simple link is applied to the physical world with a QR code).

Level 1: AR with markers (markers are employed over which the digital information is overlapped).

Level 2: AR without markers (image recognition and other techniques are used to overlap digital information).

Level 3: Augmented vision (the next stage of development of AR: intelligent glasses or contact lenses) (Sánchez 2018, p. 21).

Cozar et al. (2015, p. 143) state that the advantages of using AR in education in general revolve around the following aspects:

- Development of cognitive, spatial, perception, motor and temporal abilities of the students, independent of their age and academic level
- Reenforcing attention, concentration, short-term memory and long-term memory in their visual and listening forms, as well as reasoning
- Activation of cognitive processes of learning. AR works in an active and conscious manner on these processes because it allows for the confirming, refuting, or broadening of knowledge and generates new ideas, feelings, or opinions about the world
- Creation of attitudes of reflection when explaining the phenomena observed or to bring solutions to specific problems
- Supplies an efficient environment of communication for educational work, as it reduces the uncertainty of knowledge about an object
- Increases the positive attitude of the students about learning, as well as their motivation or interest on the subject that is being addressed, reenforcing abilities and competences (independence, initiative, and principle of self-activity or independent work)

All of these have an important presence in the inclusive education sphere, and many research studies have studied this. For example, the Chen

et al. (2016) study showed the possibility of using them with autistic children, or the study by McMahon et al. (2015), which presented their advances also with autistic children, besides those with intellectual disabilities. The study by Lin and Chang (2015) explored uses with children with intellectual disabilities, as well as interculturalism and multiculturalism, visual, motor, psychological, and hearing disabilities, or those with high abilities (Cozar et al. 2015; Wojciechowski and Cellary 2013; Marín 2016, 2017). Juan et al. (2014) point out that AR supports spatial memory at the children's education stage, as well as for students with diverse disabilities.

On the other hand, the issues concerned with uses of AR can be identified in the education sphere as lack of teacher's training; lack of resources; lack of time; or the digital divide it creates (Marín 2016, 2017). Nevertheless, the possible positive results of their utilization have greater weight, with this being the reason for its fast penetration.

Focusing interest on the options that can more easily be accessed, at level 0, the use of QR (Quick Response) codes, can be defined as "a two-dimensional matrix of dots that can store a great quantity of information within it" (Sánchez 2018, p. 22). This allows storing a great quantity of information in two dimensions (horizontal and vertical), with this information being videos, images, sound, text, and so on. The main advantage of a QR code is its easy creation.

There are a great number of generator sites on the Web, such as Unitag (<https://www.unitag.io/es/qrcode>), or QR Code Generator (<https://es.qrcode-generator.com>). It should not be forgotten that QR codes can be dynamic or static, with the latter category being more common, and the easiest to create, and the applications – or at least most of them – tending to be free, although some have to be paid for as well. On the other hand, the dynamic ones can be modified many times once the code has been created, while the static ones cannot. Nevertheless, the colors and images used to create them should be taken into account, as the code can become illegible. For example, in the case of Fig. 8, the code with an image cannot be

read by part of the readers. Also, the logo of the business/NGO/association, where the user is collaborating/working, can be incorporated into it (Fig. 9).

Among the choices that can be found for working with AR in inclusive education environments, is the project *Pictogram Room* (<http://www.pictogramas.org/proom/loggined.do>), developed by the Polytechnic University of Valencia and the Orange Foundation. As found on its web page, this project “is an entertaining way of making advances in basic aspects of communication, joint attention, the body’s scheme and imitation. Through visual and musical supports, the child or adult have available different

video games with which to learn, taking advantage of its strong characteristics: the visual character of the games, the music and the use of the body.”

“Pictogram Room is a set of entertainment-educational activities that are free to download, designed to provide an answer to a series of needs of people with Autism Spectrum Disorder (ASD), which up to the present has been difficult to deal with. Difficulties in the understanding of the body language, its recognition, imitation or joint attention. . . are critical abilities for the development of the child with ASD. This can be addressed in a fun manner within Pictogram Room, where the children and adults with autism, with the support of the educator and also accompanied with other children with autism, are entertained by playing” (Pictogram Room 2018).

On the other hand, the new application that Google has linked to AR, Google Arts & Culture (<https://artsandculture.google.com/>), works with the arts. This application places the spectator inside 360° views, where the user can enjoy, for example, a tour of the ocean depths in the era of the dinosaurs, or tour a museum room also in 360° (see Fig. 10), or make a selfie and find similar faces in works of art. Alternatively, it is possible to visit a location such as the London Natural Museum of History (see Fig. 11) (<https://artsandculture.google.com/project/360-videos>). All of the tools implemented by this application can be employed with all students, except for perhaps those who have limited vision or blindness, except for those for whom the pictures that

have the option “Amplify” allows for viewing amplified images (see Fig. 12).

A new experience that has arrived in the Latin-American context is the museum TRICKEYE, which began in Singapore and has currently opened its doors in Mexico City (<http://www.trickeye.com/mexico/ARFeature>). This museum

allows the visitor to experience the works of art that are shown “by himself or herself.” For this, the Trompe-l’oeil picture technique is used. With images in 4 dimensions and with different perspectives, the visitor can play with them and experience a work of art in the first person (see Fig. 13).

ICT-Based Inclusive Education, Fig. 12 Amplified works of art

ICT-Based Inclusive Education, Fig. 13 Web page of the TRICKEYE-México museum

The visitor can download an app to be able to project the work of art that is shown in the museum as a marker and “experience” what is shown in the museum in the first person (in its own body and minds). In this sense, and although this could be considered an innovation, individuals with certain disabilities cannot yet enjoy these new experiences.

Nevertheless, despite there being many advances in this field, works such as those by Chiang et al. (2014) and Marín (2016, 2017) have shown that in general, AR is not a valid tool for being used with the visually disabled. However, Caltech has created CARA (Cognitive Augmented Reality Assistant), based on the AR glasses from Microsoft, *Hololens* (see Fig. 14), which will be used by the US army in their training programs.

It should be noted that the Google tool also allows people with limited vision to enjoy the picture works of art, as it incorporates the image

zoom tool, along the line of the results from the work by Lin et al. (2015).

Other Inclusive Education Resources

Artificial intelligence has brought deaf or children with limited hearing closer to reading. The Huawei initiative, *StorySign*, through the free download of an app created for this, allows for the accessing of a library of children’s books, for their later downloading and reading through Star, an avatar who reads the book using sign language (see Fig. 15). This app is available in Google’s Play Store and Huawei’s AppGallery. The books are found in 10 different languages, among which are Spanish, English and French.

An example that makes learning attractive, given that students are initiated on the knowledge of the letters, written as well as spoken, is the resource Literacycenter (http://www.literacycenter.net/lessonview_es.php#), which will

ICT-Based Inclusive Education,

Fig. 14 Hololens

ICT-Based Inclusive Education,

Fig. 15 Star

encourage the acquisition of writing and the speaking of the letters and words in English, Spanish, French, and German.

It is possible to also learn by playing video games, as argued by the group Game Accessibility (<http://game-accessibility.com/game/>). From this perspective, the web page invites the user to delve into the education world through gamification (use of commercial video games not designed for educational use, but those that can be utilized for this) (see Fig. 16).

A stated useful practice of inclusiveness is one that employs video games for the following:

1. Actions that promote learning and achieving of objectives
2. Seeking a high educational level
3. Achieving a lower rate of school rejection
4. Providing a greater depth of/in learning
5. Promoting the inclusion of diverse collectives
6. Developing diverse abilities and skills

7. Invigorating the relationships between members

8. Introducing values and processes of reflection

9. Offering diverse competences

Conclusions

It is well recognized that ICT will not substitute for a teacher but, on the contrary, should be understood and accepted as an element that mediates the processes of teaching and learning (Romero et al. 2018), given that when ICT is incorporated into the area of inclusion, challenging spaces are promoted that can call into question the principle of equality that inclusive education seeks.

Promoting learning and the collaboration between subjects, mediated by today's digital tools, allows for social interactivity, and as a result, the development of a digital inclusive

ICT-Based Inclusive Education, Fig. 16 Game Accessibility portal. (Source: <http://game-accessibility.com/game/>)

education. This is based on the belief that all technological resources will and should be understood, utilized and made available to and for all, independently of the physical, psychological, social, economic, or educational situation they are found in.

Education professionals, as pointed out by Gelastopoulou and Kourbetis (2017), feel the need to incorporate ICT in general, and Web tools in particular, to their day-to-day practice. As Marín (2018) indicates, “the ICT-inclusive education pairing leads us to think about two elements that must converge strongly for a single aim: the improvement of the training of the individuals in general and of society at large. This

improvement should begin from a new approach that will appear from the figure of the teacher, mainly,” and this is where all efforts must come together, as what is transmitted can be what is felt and thought, in terms of concerns, efforts and beliefs, as well as values, and countervales, and this is why this matrimony is “obligatory,” to understand each other.

E-inclusion must allow for the evolution and growth of every education system, so that it can be understood as an element that is inherent to the system itself; ergo, the design of actions that do not promote digital equality should be avoided, in favor of a society that is just and egalitarian.

Overview

In this document we will address how secondary schools (with pupils in the age of 12–18) can implement ICT in their educational system. We will use three different models or frameworks to guide such implementation. At first we distinguish between two ways of looking at ICT in education. On the one hand, educators can use ICT to improve the quality of the educational setting and the learning outcome. On the other hand, ICT should be regarded as a subject in the curriculum: learning about informatics, computer science and information literacy, and developing ICT skills. Being aware of the differences between those two ways of looking at ICT in education, we can use a model for implementation which will be described in Chapter 2. The model consists of five phases of awareness, involvement, and consequences, elaborated on in a paper written for and commissioned by UNESCO (Hogenbirk):

1. Phase 1 is the acknowledgement that ICT is a not negotiable, integral part of the learning environment in the education of the twenty-first century.
2. In phase 2 we focus on the learning *about* ICT and ICT skills. In this phase we address ICT literacy culminating in computer science or informatics. But we will also look at the so-called twenty-first-century skills, in which ICT skills play an important role.
3. Consequently or parallel teachers are using ICT in the classroom as a pedagogical tool: learning supported by ICT. Phase 3 concerns a modest way of usage by the teacher him/herself and by the pupils at home. This is a substitution stage of using ICT in the pedagogical process.
4. A next phase is the widespread usage of ICT within the classroom by the pupils and the teacher in a variety of learning activities. This is an integrating stage of using ICT in the pedagogical process.
5. Finally ICT can change the organization of education, by personalization of the learning process. We could call this the transformation stage.

In the chapter “Four in Balance, a Model for Actual Development of ICT-Rich Education at School” we will go into more detail about the conditions of implementing ICT in education. We will use an approach in which four sets of conditions should be in balance with each other, the “Four in Balance Model.” This model is developed by Kennisnet, the Dutch National Centre of ICT in Education (Kennisnet, see <https://www.kennisnet.nl/about-us/>).

Schools should have a vision on the usage of ICT in terms of the objectives they want to serve with it, how they want to use it, and what results they want to accomplish. Secondly the professional development of the teachers should be in line with the formulated vision. Thirdly the software tools should fit the requirements needed. Fourthly, the hardware infrastructure should be sufficient and adequate to accommodate what is necessary.

Finally we will present in the chapter “The P2V Framework for ICT Implementation” a framework for the assessment of the state of ICT implementation in a particular school, to be used by external inspectors or as a self-assessment tool by the school itself. This framework was developed in the European P2V project (Peer to Peer networking for Valorisation) performed by several European school inspectorates (van Oel et al. 2009a).

Introduction

Starting in the early 1980s of the past century, the educational community – practitioners, teacher trainers, and educational researchers – has been working on the introduction and implementation of computers in education. These efforts were attached to the notion that society was entering a new phase. Beniger (1986, From the lemma: “Information Society” in Wikipedia.) showed that the term “information society” was one of the many notions used to described this change from an industrial society to a society where information plays a dominant role in economics, politics, culture, and education.

At first, there were attempts to familiarize young pupils with the achievements of the “new era.” Educational materials were written to practice working with computers; educational software was developed for applying in the different disciplines; national projects were established to supply schools with computers, mostly in separate computer labs; and courses were given to make teachers familiar with the new technical and didactical aspects of computers and educational software.

There were two main reasons for all these activities:

1. Pupils should learn to be skilled in using information technology (IT at that time) as part of the core curriculum (“computer literacy”).
2. At least politicians and educational forerunners thought that IT could improve the outcome of the educational process (and as a side effect, make education less expensive). This type of support by IT was called CAL, computer-aided learning.

In these two objectives, we already see the distinction between learning *about* IT and learning *by means of* IT.

In the 1990s, the Internet popped up as a source of information. Windows brought a much more attractive design for the software. Computers appeared in the classroom – at the back of the room or at the teacher’s desk. Projectors could be used for demonstration purposes. Administrative software was developed and replaced written reports. Assessment tools became available, electronic calculators changed the mathematics curriculum, and word processors made spelling less relevant. IT became ICT! It was not any longer only about the rather static use of data and information, but the digital revolution also changed the way of communicating.

In many countries politicians declared the usage of ICT in education as an inevitable and thus “normal” way of doing in education. But they forgot that principals, teachers, parents (!), and perhaps also the students did not recognize that importance in the same way, and the full

implementation of ICT in daily practice in the classroom did not take place.

In the present decade of the twenty-first century, the smartphone was developed, appearing in every child’s pocket, social media became very important and sometimes dominant, and the information within the Internet is overwhelming: the usage of ICT in daily life indeed became “normal” and inevitable. Nevertheless schools are still wrestling with questions about the necessity, the usability, the effectiveness, and the reliability of using ICT in the educational process, and thus we still see a lot of schooling activities where ICT do not play any role at all.

There is still debate: some doubt if the school should not just resist to the use of ICT in the safe and protected environment of the school. Educational experts investigate the added value of educational computer programs but are hardly capable of “proving” the positive effects. The investments of schools in ICT infrastructure are enormous, and the vulnerability of the systems is a threat for a continuous and stable educational environment. So it may be a good moment to mark time and consider carefully why we should invest in the usage of ICT in education.

Five Implementation Phases of ICT Awareness and Involvement and Their Consequences

We will present a model with five phases, stages, and consecutive argumentations for using ICT in education. We developed this model in a paper commissioned by the UNESCO (Hogenbirk) and applied the model in several cases of advisory processes with individual schools. It brings clarity to the management of schools in where they stand in their implementation process and what they can do to bring that process forward. The phases presented are not necessarily following each other chronologically. Also they are not scientifically independent. They actually address different perspectives of ICT usage in education. Nevertheless they represent in the presented order more or less the recent history of the development of ICT in education and in most cases the way the

implementation process in particular schools develops. In all phases we will give some examples to clarify and illuminate the nature of that phase.

We will begin with the phase in which we acknowledge the necessity of bringing ICT into our schools.

ICT in Education Is Not a Choice

Society is rapidly changing due to the tremendous impact of ICT used by almost all people, including of course the youngsters in our educational system, often referred to as the “digital natives” (Prensky 2001); “Generation Z” (see e.g., generationz.com.au/characteristics), for young people born between 1995 and 2009; and the “Net Generation” for pupils who are now growing up. McCrindle (2014, <http://mccrindle.com.au/the-mccrindle-blog/what-comes-after-generation-z-introducing-generation-alpha> with illustrative infographics) uses the notion of “Generation Alpha.”

The use of ICT influences to a very high level the lives of the kids who are present now in our educational system. The communication between them, the way they play, the information through the media, and the way they are looking at themselves and at their peers and relatives are greatly influenced by ICT in all forms available: computers, tablets, smartphones, the Internet, apps, social media, etc. There is a lot of positive interaction and communication about things happening in their daily lives (yes, also about school-related issues). But also bullying is done digitally. Lover boys are operating by smartphones and dating sites, and digital fake news is a new word for an old phenomenon.

All of this cannot remain without consequences for education. Pupils growing up in the twenty-first century would consider a school without ICT as an unworldly situation. And it is probably just for this reason that, all over the world, initiatives are emerging to turn over the ways we educate. A class full of youngsters, growing up with new technology all around them, cannot be approached by old-fashioned methods, learning materials, and curricula. In a new learning environment, ICT should play a significant role,

clockwise or counterclockwise. So we would state here that education and ICT are an enforced marriage. All other reasons to use ICT are arising from this first notion: we cannot place teaching and learning in an environment that is not mirroring and reflecting the world outside the walls of the school.

It is good to articulate this premise here again clearly, because there are opposing views. One of the most well-known is the view of the German sociologist and pedagogic Thomas Ziehe (1999) who has been fighting since the 1970s for an education that offers students insights and methods just disconnected from their experiences outside the school, called “Alltagserfahrungen.” This kind of noise is also heard in columns in the newspapers and in associations of concerned parents and teachers, with reference to their own childhood and the – often idealized – past.

From the foregoing it will be clear that we should regard these views as background battles, comparable with opposing the (“pernicious”) art of printing in the fifteenth century, the (“dangerous”) transport by train in the nineteenth century, and the (“hazardous”) driving in an automobile or watching television in the twentieth century.

In our view the educational community is obliged to itself to explore new paths for teaching and learning, with conservation of the numerous good elements within the traditional ways of teaching and learning. But only acknowledging this is not enough to fulfill phase 1 in our model. The notion presented here should be reflected in a preamble of the school vision on the way education should be performed, supported by ICT, in a particular school. And this preamble in the vision should be attached to other principles and starting points of the school’s pedagogical identity.

ICT as an Objective of Its Own

Since we now have established the absolute necessity for an ICT-rich learning environment, the need arises to give attention to learning *about* ICT and the development of ICT skills. Of course this is not a new sound. Since the 1970s, the educational community has been discussing the character of insights, knowledge, and skills of ICT

or ICTs. The names of the learning area vary and evolve. We have to distinguish between lower and higher secondary education.

Digital Literacy in Lower Secondary Education

In lower secondary the original name “computer literacy” has been replaced by “information literacy,” “media literacy,” or “digital literacy.” This area consists of a series of communication competencies, including the ability to access, analyze, evaluate, and communicate information in a variety of forms, print and nonprint including messages and also moral and ethical issues concerning the use of social media and the Internet (NAMLE, see National Association for Media Literacy Education, <http://namle.net/publications/media-literacy-definitions>). There are numerous descriptions of the content of this subject. Good examples are the new curriculum that has been developed recently in Australia (2013) or the somewhat older Standards for Technological Literacy from the International Technology and Engineering Educators Association, ITEEA (2006). Other recent examples are from the British Open University with the publication “Integrating IL booklet” (2010) and the ANCIL project with a description of information literacy (2011).

Twenty-First-Century Skills

Another way of addressing the skills involved in this subject area is to consider them as part of the so-called twenty-first-century competences. The European Union published a set of eight competences which cover a wide area of education as a whole (2006): communication in mother tongue, communication in foreign languages, mathematical competence and basic competences in science and technology, digital competence, learning to learn, social and civic competences, sense of initiative and entrepreneurship, and cultural awareness and expression. Organizations like Partnership for 21st Century Skills (P21, Partnership for 21st Century Skills, see www.p21.org), NET/ISTE with the National Educational Technology Standards (2007), and Assessment and Teaching of 21st Century Skills (ATCS, see [http://www.microsoft.com/education/en-eg/leadership/Pages/](http://www.microsoft.com/education/en-eg/leadership/Pages/assessment.aspx)

[assessment.aspx](http://www.microsoft.com/education/en-eg/leadership/Pages/assessment.aspx)) have performed research in the past years to establish the “ultimate set” of competences needed for the twenty-first century. Voogt and Pareja Roblin (2010) concluded in a comparative analysis that all of these studies have in common that they focus on conceptual and meta-cognitive knowledge and skills with respect to communication, collaboration, socio-cultural awareness, and ICT skills.

Comparing the different views and approaches on these competences, we defined four more or less distinct areas of competences (Hogenbirk):

1. Learning and thinking skills: critical thinking, problem-solving, learning to learn, creativity, and imagination
2. Social skills: communication, collaboration, responsibility, and accountability
3. ICT skills: information, media, and technological literacy
4. Life and career skills: citizenship, cultural awareness, self-regulation, and leadership

So if a school is paying attention to ICT skills, the school is also showing commitment to the wide scale of competences needed to be a responsible and well-prepared citizen and worker in the fast-changing future.

In most countries there are objectives, a curriculum, and materials available for teaching and learning this particular area (OECD 2006). However there is often a debate about the way the subject should be taught and the skills should be developed in schools. The core of this debate is if these objectives should be taught as a separate subject with a specialized teacher or if they should be part of and integrated in other subjects, such as mathematics, sciences, social studies, and even arts. At this moment in a lot of countries, the pendulum is at the side where governmental bodies recognize the necessity of some kind of obligatory curriculum on information literacy. Although pupils might be “digital native,” it seems more necessary than ever for children to learn how to deal with information, which ethical and legal aspects of digital information are involved, how to deal with social media on issues such as bullying or privacy, and how to guard

themselves against being constantly online and therefore not being able to concentrate on a more difficult learning task.

In cases where there is no hard curricular obligation from the government to teach the subject separately, we advocate here to consider carefully at the school level if there is a need for a separate discipline with separate teaching classes or if the school and the teachers are able to collaborate on integration of ICT and ICT skills in different existing subjects.

Computer Science

In higher secondary education, the situation is a bit different. Mostly it is expected that pupils already have enough basic skills and knowledge on the use of ICT. What remains here is the somewhat “harder” side of ICT: “computer science” or preferably “informatics,” sometimes referred to as “computational thinking” (Wing 2006), which consists of programming and logical, algorithmic thinking. Other parts of this separate discipline are the hardware technology, information and (big) data analysis, security issues, robotics, and the Internet of Things.

In best cases informatics is offered at higher secondary schools as a nonobligatory choice discipline.

Conclusive Remarks

Defining ICT content and competences on different levels is a major task. First of all because we are talking here about a very fast evolving and changing area of content and applications which makes the educational assignment for every school extremely complicated. It is about creating an environment and a curriculum where all of these skills and content can be practiced, developed, and finally assessed, and choosing carefully what elements should be obligatory and which should be free to choose.

Curriculum elements in which these skills are taught and in which they play a massive role can be found in all subjects in secondary education, in project-based education, in inquiry-based learning, and in more informal outside-school learning activities like excursions and internships. In most of these curriculum elements, ICT plays a

supportive or even dominant role. So the boundary between teaching and learning these skills and using ICT for enhancement of the learning in general is in most cases not very strict. That brings us to the third phase of looking at the implementation of ICT.

ICT Usage for Enhancement of Teaching and Learning: Substitution

So far the reasoning in this entry to use ICT in education is as follows:

- Children are facing and living in a new ICT-rich outside world. To reflect this world and to prepare them properly for a life after school, we are obliged to deliver an ICT-rich learning environment.
- Children should be able to handle ICT within this learning environment and outside school. For that reason, ICT skills must be taught: to handle information, to be able to use computer programs, and to have some awareness in computational thinking.
- In the society of the twenty-first century, traditional knowledge is not enough. ICT skills are part of a bigger collection of the so-called twenty-first-century skills, which have to play a much more prominent role in the teaching and learning practice.
- To design that practice, we have to integrate the use of ICT in every learning situation where it is possible and appropriate.

Recognizing ICT usage as a profitable tool in education leads to the question how far this usage goes. The range of activities where ICT can be used for pedagogical purposes is enormous. In this third phase of looking at it, we focus on the pedagogical use of ICT by teachers in their classes and by pupils doing homework. It is a phase of mostly substituting traditional pedagogics by ICT applications. ICT is mainly used for illuminating specific topics. A biology teacher presents a short movie about the way penguins live, a geography teacher shows a digital map on the screen, in physical education the perfect Fosbury Flop is shown on YouTube, and in art classes paintings can be discussed

with the whole class. Teachers can project the timetable of the class or a specific assignment on the screen, which they have prepared at home, and with no waste of time in the classroom.

The advantages of this type of usage are obvious: it is easy doing, motivating, clarifying, clear, and cost-effective. Although the last advantage could be questioned, because the projector is an investment, the bulb has to be replaced, there has to be Internet connection for some purposes, you always have to be prepared for a failure of the equipment, and there is a need for technical assistance. Giving pupils digital assignments for homework is also part of this phase. Sometimes one can make use of digital add-ons to courses in print, sometimes called “iPacks” or “e-packs.” Author teams of educational textbooks have made strong efforts to invigorate their courses with ICT assignments, graphics, exercises, short movies, etc. The advantages are easy to determine. The teacher can still use “old-fashioned” materials, within his or her traditional approach. It is easy to use these little extras for homework, lost moments in the classes, and extra work for remedial or deepening usage. It has also been the ultimate reaction of the educational publishers to this innovation of their text-based learning materials. They do not have to change their business models completely and can just go on selling books as they were used to. But is this way of using ICT enough? ICT is playing a marginal role in the teaching and learning. It just modernizes the traditional teaching and learning a bit.

By using ICT in this way, one is *substituting* traditional teaching and learning methods and materials by somewhat more contemporary means, but, in essence, not much changes.

ICT Usage for Enhancement of Teaching and Learning: Integration

A next phase in using ICT for pedagogical purposes is to really *integrate* software in the teaching and learning process. The difference with phase 3: substitution is that this type of usage is really changing the pedagogy, often leading to other learning outcome and surely motivating

the learners in a way they are used to outside of the school. We will give some examples of ICT applications a teacher can use.

Educational Software

At first there are specific educational programs. Examples are numerable. See, e.g., the list for educational programs on Wikipedia (2006–2017, see e.g., http://en.wikipedia.org/wiki/List_of_educational_software). Simple programs can be used for exercising foreign language words, topography, historic timelines, chemical reactions, fill in exercises, texts with missing words, multiple-choice quizzes, etc.

Complete and more open environments are available, e.g., in mathematics, to practice calculating, to draw graphs, to explore geometric figures, and to make algebraic or statistical calculations; in music we have the composing programs, and in physics there is software for constructing electrical circuits or controlling and measuring physical phenomena, and there are drawing programs, programs for book-keeping, etc.

There is hardly any debate on the benefits of these types of programs. They are efficient in using and easy to handle and set up, and they make learning activities possible that were far out of reach before.

Simulation Software

A special category of educational programs are the simulation games. The term “gamification” describes situations in which game thinking and game mechanics are used in nongame contexts such as education. Subcategories are adventure games, puzzle games, role-playing games, strategy games, sports games, and even first-person shooter games (Oblinger 2006). Examples of simulation games are text adventure games, SimCity, a blood typing game, management and business simulations, global warming, soccer playing, etc.

Benefits of using games in an educational setting have been measured when the games are used in a proper context, for a specific goal (Griffiths 2002). They can increase student motivation, stimulate interaction and discussion between

students, and place learning stuff into a broader and more relevant context.

Generic Software

While almost all of the programs mentioned here are dedicated to one specific discipline, subject, or curriculum element, a more general way of integrating ICT in the classroom is the application of generic tools. This category contains the word processors, spreadsheets, and presentation tools. Even more generic is the usage of programs like Google apps, Dropbox, etc.

There are also generic programs, especially developed for usage in education. First of all there is the digital assessment software. In this category we find dedicated tests, sometimes as a part of specific learning material. Very usable are the general sites for training exam tests. Thousands of students know how to find these sites without any advice from the teacher. At the other end of the spectrum, we find open assessment tools in which one can import professional tests or in which teachers can develop tests themselves. There exist free to use programs like Testmoz or Questbase and more sophisticated commercial programs like Question Mark and Quayn. Sometimes assessment tools are integrated in the more complete digital learning environment, which will be discussed in paragraph 2.5, because it influences the organization of the teaching and learning.

Other examples of generic programs are Socrative, which enables teachers to engage their students in a class discussion being active with their tablets, laptops, or even smartphones by real-time questioning and visualizing the results; MindMeister, which enables teacher and students to make mind maps of their ideas, foreknowledge, solutions, and brainstorming; and StickyMoose, a tool for collaborative decision-making; etc.

When we look at the usage of iPads, a lot of generic tools are available. We mention some examples: Book Creator or iBook to make your own teaching material or for kids to make their own reports of a project; Explain Everything for writing and importing images and video in one

environment; Vittle Free, which is an interactive whiteboard video recorder to teach concepts and show presentations; iMovie to make or use videos; GarageBand to compose and make music; etc.

The advantage of open generic software is indeed the fact that it is open: teachers and students can use it for multiple purposes, at school and at home, at moments they can choose themselves. You may see in schools that pupils are just using this software at their own convenience. This usage contributes to the more or less informal learning of ICT skills or the informal achievement of ICT objectives (from phase 2 in the model we use).

The Results of Using ICT

At this point we should pay attention a bit to the effects of using ICT tools in the pedagogical teaching and learning environment. Over the past 30 years, a lot of research has been conducted to “prove” the positive effects of ICT on the learning outcome. Well-known is the work of John Hattie who studied 76 meta-analyses of almost 4500 papers using statistical methods to compare the effectiveness of all kinds of teaching and learning strategies and circumstantial conditions (Hattie 2009). In this meta-analysis, research on the effect of ICT usage is very well represented. Yet in his “top ten” of aspects which are most effective, the use of ICT *as such* is not mentioned. But indirectly one can say that some teaching strategies do benefit from the use of ICT. In a comment Steve Moss (2014) identifies six aspects from Hattie’s study which should have most effect on the learning outcome. And for educationalists, these aspects are not really surprising: diversity of teaching strategies, multiple opportunities for learning, students having control of their own learning, and peer-learning and feedback mechanisms which should be optimized to gain maximum outcome. This leads to the conclusion that it is the (difficult but challenging) assignment of practitioners and researchers in education to find the best ways of using ICT for enabling these types of pedagogical success factors.

ICT Use for Changing the Organization of Learning: Transformation

The boundaries between the different types of using ICT and accessory objectives are not always strictly determinable. Yet there is another category of programs and digital environments which is primarily meant to be used as a tool supportive to the organization of the teaching and learning process. It is emphasized here that this type of use could be the most far-reaching. It really could change long-lasting traditional paradigms in education and contribute to the aspects that were mentioned in the previous paragraph that are most effective to improve the learning outcome. So we call this usage of ICT *transformative*.

Two basic leading principles could change the traditional way of teaching. The first is the recognition that every child is unique. So teaching is most effective if it meets the individual needs of the students and if the responsibility of the learning is basically given to the learners themselves.

The second basic principle is that collaborative learning (or peer learning, group work) is an effective way to organize learning situations. In the contemporary reality of schools, these principles are hard to realize. Many factors, such as class size, available, often scheduled time, and lack of usable learning materials, hinder teachers to respond to differences between pupils and make collaborative arrangements impossible. We will elaborate a bit on both principles in relation to the use of ICT and also try to combine the principles because at first sight they may seem a bit contrary to each other.

Personalization

The UNESCO Policy Brief on personalized learning (Izmestiev 2012) presents different definitions of personalized learning. Here we will use the following definition:

Personalized learning is a way of organizing the learning process in terms of content, learning environment, and learning outcome, so that it meets the personal (cognitive) abilities, learning

style, interest, and context of the learner in the best way possible.

Personalized learning can be accomplished in three different stages: working independently, independent learning, and self-responsible learning. In the first stage pupils work on their own assignments given by the teacher. If the students themselves are in control of the way they want to achieve the learning goals, we call it independent learning. What the goals are and how they are assessed are still determined by the teacher. Finally self-responsible learning is the situation in which students determine themselves (part of) the objectives and the way the assessment takes place.

In all of these different stages, ICT can play a crucial role to realize personal learning paths. Let us sum up the advantages of this way of organizing the learning:

- Students can learn on their own level of cognition; this also means that learners do not need to be put together in homogeneous groups; pupils of different ages and abilities can be mixed up and work side by side to each other.
- The learning is less bound by time and place; even holidays can be customized to the wishes of parents and to the need of the children.
- Various learning styles and various interests can be accommodated.
- Because of these aspects, the learner's motivation will increase.
- The learning can be recorded and constantly monitored by the pupils themselves, by teachers, and/or by the parents.
- If these data are correctly analyzed, the learning can be made much more adaptive to pace and level of the pupil and make suggestions for the next steps or interventions in the educational process; in this context we speak of a new area of expertise: the so-called learning analytics.
- If performed with a proper setup and accompanied by proper coaching, the students can better understand their own learning and develop the valuable competence of "learning to learn."

Collaboration

Personalization does not mean that all learning activities should be strictly individual. On the contrary, many activities could be carried out collaboratively, in social and/or intellectual peer groups. Also in peer groups, the nature, level, and pace of the assignments can be harmonized with the individual demands of the learner. In fact we can distinguish here similar stages of involvement like we did for personalization: we can organize cooperative working when students are allowed to work together on a certain assignment. If the way of performing a learning task is left to the group, we call it collaborative learning. If the group decides itself about the content, methodology, and way of presenting the outcome, we could speak of learning with collective responsibility.

Some schools experimenting with different types of learning, individually and collaboratively, have built common educational areas, sometimes called “learning squares.” In those areas pupils of different levels and ages are mixed, working alone or together on different tasks. Teachers and other coaches are walking around to give support and ask the right questions.

ICT Arrangements for Reorganizing the Learning, E-Learning

Having set the two basic principles of new ways of learning, we can search for using ICT in these settings. If the learning is completely ICT-driven, we speak of e-learning. A new methodology for that is the MOOC, the massive open online course. This is an online course aimed at open participation for all through the web. Some MOOCs provide additionally communities for interaction between learners and teachers. This way of learning is a new phenomenon used at open universities and commercial training, but not too much in secondary education. MOOCs are new, and therefore there is not much research available on their outcome and effectiveness. First experiences tend to the conclusion that it takes very self-responsible learners to perform a MOOC until the very end. Less extended ways of online learning can be found, for instance, at the Khan Academy where more than 150,000

smaller and larger courses at all levels are provided.

Blended Learning

In basic education e-learning is still not very much used. The reasons are well-known. Schools are held responsible to a large extent for the learning outcome, often have to deliver according to the law a specific amount of education time, and therefore hesitate to hand over the responsibility for the learning to the children.

But as we have seen, it could be very profitable for the learning effectiveness just to do that. And there we arrive at the term blended learning. In most cases this is defined as a mix of traditional and online or ICT-driven educational settings. Furthermore Oliver and Trigwell, who presented the term first, point out that blended learning also involves different types of instruction, behavioral principles, and strategies (2005).

Of course all sorts of educational software mentioned in the previous paragraph can be used in different intensities in teaching and learning settings. This intensity determines if one would call the learning blended or just traditional with a modern flavor.

Digital Learning Environment

Personalization and customizing the learning to the learner could also be derived from the intensity with which a digital learning environment (DLE) is used by the school or the individual teacher. Such an environment enables teachers to plan lessons and homework, to set up individual or collaborative assignments and tests, and to monitor results and learning reflections. DLEs are not new. In 1997 we already presented a model for “An educational tool for planning and monitoring the teaching-learning process in Dutch secondary education” (Hogenbirk 1997). Despite a lot of effort, the actual construction of the tool never took place.

Now there are numerous DLEs available. Because of high development costs, most of them are commercial. Moodle is a well-known DLE, free of charge. iTunes U for iPads makes it possible to present all kinds of assignments and materials to the learners and colleagues in and

outside the school. ZuluDesk Teacher is a mobile device management tool for iPads with which teachers can manage the learning at the students' devices.

The functionality of DLEs differs. At a minimum level they comprise the possibility of planning, arranging, and supporting the teaching and learning process. They differ in the way they offer the possibility to arrange different learning paths, to approach learners individually, to use portfolio facilities, and to monitor results through learner tracking and management reporting tools. Especially the portfolio functionality is important. A portfolio allows students to store their learning activities, to present results, and to reflect on their own process. Just those features make a portfolio suitable for self-responsible learning.

Flipped Classroom

Another very promising way to change the organization of the teaching is the flipped classroom. In essence this is a form of blended learning where instruction and processing are interchanged. The homework consists of the watching of an explanation or instruction of a certain phenomenon before the school class starts. In the class students can work out assignments with the things they learned in the video with guidance from the teacher, or they can have extra instruction or explanation. There has not been done much research yet about the learning effectiveness. Jensen et al. (2015) found that the "flip" as such does not benefit the learning. But in this research arrangement, the flipped classroom was embedded in a constructivist pedagogy, meaning that students were actively engaged in the material. And this combination leads to improvement of the learning results.

Internationalization

In order to match the goal of citizenship and cultural understanding, it is useful to mention collaborative international projects for children. Initiatives as iEARN (worldwide) and eTwinning (in Europe) provide many possibilities for projects where pupils collaboratively work together on a certain topic. In a "whole

school approach," there is also a collaboration between teachers of different disciplines and levels to manage and coach multidisciplinary and multilevel projects (Galvin et al. 2007). This type of education is different from traditional methods. It leads to unexpected learning outcomes and is therefore hard to assess. The projects are also quite time-consuming for both teachers and students. But the rewards are tremendous as masses of products and proud students in movies on the web prove.

Pupils: It Kicks

Finally in this entry, we want to suggest reading a little booklet called *Pupils: It kicks* (Hogenbirk, de Rijcke 2006). This gives some examples in Dutch secondary education of new ways of learning with ICT. In the booklet a model is presented which characterizes educational settings along three dimensions. The first one is the axe of the learning context. This varies from theory-based (the subject is the core) to practice-based (applications and practical issues are central). The second dimension is the extent to which the pupils are self-responsible for their learning. It varies from teacher's determination up till the situation where pupils are fully in charge themselves. The third dimension is the pedagogical relationship: from the subject-expert role up till the coaching guiding role.

Conclusive Remarks

It is an understatement to say that there are some challenges to meet when transforming the traditional pedagogical environment into a more self-driven, personalized, and collaborative ICT-supported learning environment. In Hogenbirk (2016) we elaborate on five issues:

- Individual self-responsibility for the learning needs an intrinsic school vision on the position of the learner and the teacher.
- Often the prevailing national curriculum or exam requirements hinder the possibilities for own learner or teacher choices.
- The learning materials and the way ICT is used in such an innovative learning environment have to be tailor-made and adapted for the

specific subjects, for specific groups of pupils, and for the different levels.

- There must be very much attention for teacher training and development because most teachers love to be the expert in their subject and love to demonstrate that; instead here they have to evolve to a more coaching and guiding role, even develop a learning attitude themselves if they are not in charge of the choice of content anymore.
- The final performance of the pupils will be the ultimate determination of the value and validity of these kinds of new teaching and learning arrangements.

Four in Balance, a Model for Actual Development of ICT-Rich Education at School

To help schools to implement the use of ICT, some frameworks and models can be used. In this entry we will explain the so-called “Four in Balance Model” which aims at a balance between school vision, professional development of teachers, digital content, and infrastructure. This model is developed by the research department of Kennisnet, the Dutch National Centre of ICT in Education, and also used to monitor the progress in the use of ICT nationwide (Kennisnet 2015).

Vision of the School

The first pillar in this model is the vision of the school on education in general and the role of ICT to support this vision. We mentioned this in paragraph 2.1 when we were addressing the necessity of acknowledging that an educational environment without attention for ICT and without using ICT is impossible in the era in which we live. In the vision of the school, this acceptance should be the starting point, further elaborated in school-specific objectives for improving the outcome of the education.

How does one look at traditional ways of learning in relation to ICT? How would one use ICT in order to stimulate pupil’s own responsibility for the learning? How is one’s appreciation for using ICT in the balance between “hard” learning outcome,

personal development of the pupils, and the way they should be prepared for further education and future jobs? These are some examples of question to be answered in the school vision.

Professional Development of Teachers

The second pillar in the “Four in Balance Model” is the expertise of the teachers. They should be able to use ICT in their daily practice and in their own professional development. The school management should be aware of the possibilities of ICT and of the ways to support the implementation. The support staff should be able to cope with new developments and an increasing complex infrastructure and be able to use applications and hardware in their classes.

Digital Educational Content

The third pillar of the model is the availability of educational ICT application. In the description in previous paragraphs 2.3, 2.4, and 2.5, we have seen that this is about the use of subject dedicated applications, educational content of the Internet, simulations and educational games, generic software, and the DLE (digital learning environment). However in this model it is not only about the availability of the software but also about the willingness of the school to provide licenses, to maintain the software, to instruct the teachers, to provide the financial means to maintain the applications, and to provide user support.

ICT Infrastructure

The fourth pillar in the model is the infrastructure, dealing with hardware, networks and connectivity, smartboards, mobile smart phones, technical support, etc. In this domain the debate is going on if BYOD (bring your own device) is a proper development: if you can allow, or even expect or demand, that pupils use ICT devices which they bought themselves and if you can ask the teachers to be familiar with a variety of hardware in their classes. Some schools developed the CYOD concept: let the pupils choose their device from different possibilities. Of course a school could also provide the equipment for a 1:1 situation (one device for every pupil), but most schools are financially not capable to afford that luxury.

In 2012 an important extra layer was added to the model: the four pillars should not only support the primary process of the teaching and learning but also the secondary processes of organizing and managing the educational practice in schools and accounting for the outcome.

Conclusive Remarks

The “Four in Balance Model” states in principle that four pillars should be relatively balanced to each other. If a school has a perfect infrastructure, but the teachers do not know how to use the ICT, the implementation fails. If the vision is providing a clear direction for using ICT, but there is no suitable software available, successful ICT usage will not take place.

The model can illustrate two ways of working toward a more ICT-rich school environment. The one way that failed was that many schools (and national projects) started in the past with providing infrastructure and some dedicated educational courseware. At the same time these provisions were not accompanied by teacher training and were not attached to the school vision. The result was that most often the implementation failed.

More successful is that nowadays many schools formulate a vision on ICT use at first (there are much more clear images of effective and useful use of ICT), take care of sufficient knowledge and skills of the teachers, and in parallel decide which software and hardware are needed to translate the vision into practical learning activities.

So the model provides a powerful thinking frame for the actual implementation of ICT in a specific school. Schools can evaluate themselves to what extent they are fulfilling the right conditions, in balance, on all of these aspects, in relation to the phase described in Chapter 2 in this document.

The P2V Framework for ICT Implementation

In 2009 the inspectorates of the Netherlands, France, Spain, Scotland, Sweden, and Lithuania

finalized within the P2V project the European Framework for the Evaluation of ICT in Education. This framework can be used to assess a school on their level of development on ICT (van Oel et al. 2009). The framework consists of eight domains with several quality indicators in each domain.

In brief: The first domain is about leadership: Is there a vision and a strategy for implementation? The second domain concerns the infrastructure and access: Are these sufficient, suitable for the needs of the school, stable, and efficient? The third domain is about the curriculum planning: Is it coherent, balanced, and consistent? Does the curriculum meet the national requirements? The fourth domain is quality assurance and improvement: Is a cycle of quality control, evaluation, and revision used? Very important is the fifth domain: How and to what extent are the pupils using the ICT and capable of doing that? The sixth domain is the teaching process and teaching staff competence. The seventh domain concerns administrative use. The last domain is about the impact on learning and effects of ICT use on pupil attainment. This framework can be used to assess the ICT development of one particular school, either by an external body (i.e., an inspectorate) or by the school itself through a self-evaluation.

Example of Using the P2V Framework in a School

An example of a self-assessment of the implementation of ICT in a school is given in a series of papers on ICT Action School Development at Helen Parkhurst Dalton School in the Netherlands (Hogenbirk and Braak 2008, 2009, 2011). In September 2007 an assessment on ICT in education took place at this school through a visit of a group of inspectors, by using the European P2V framework. The results of this assessment were extensively described in the first paper mentioned above. We present here as an example only the assessment of the indicators within the framework in the first visit (2007) and at the state of the last self-evaluation (2011). See Table 1.

In this example one can see progress but also decline. For the management of the school and

Implementation of ICT in Secondary Schools, Table 1 ICT self-assessment September 2007 and February 2011, indicators for ICT quality

Leadership	Score 2007	Score 2011
C1.1 There is a clear vision for the use of ICT	0 1 2 3 4	0 1 2 3 4
C1.2 There is a strategy to realize the vision	0 1 2 3 4	0 1 2 3 4
Infrastructure and access	Score 2007	Score 2011
C2.1 The available resources reflect the needs and vision of the school	0 1 2 3 4	0 1 2 3 4

The indicators are assessed with the values 0 or 1 to 4. Their meaning is as follows:

0 no evidence available or not relevant

1 bad, there is hardly any positive evidence for a particular indicator

2 insufficient, there is not enough positive evidence for a particular indicator

3 sufficient, there is enough positive evidence for a particular indicator but improvement is possible

4 good, most or all evidence for a particular indicator is positive

for the people responsible for different aspects of ICT, this way of looking at your self is very valuable. It leads to debate and discussion about the causes for the assessment of the indicators and about the ways to move forward.

Conclusive Remarks

The five phases in the "Four in Balance Model," and the P2V framework are different ways to look at the implementation process in a secondary school. The first one is more or less a tool to provide insight on a bird's eye level to management and teachers of a school in the

phase of development of the school with respect to ICT.

By using the "Four in Balance Model," schools become aware of the relation between different key issues which play a role in the usage of ICT.

By using the P2V framework as a self-assessment, one can really mark the development of the school in terms of level of performance.

At different times and in different constructs, one can use one of the models to improve the implementation process. We hope that the presented models are useful to guide that process.

Introduction

Haptic technology can provide a sense of touch, either by force feedback or by different vibrations, to give different sensations to the user. It can be used in conjunction with 3D virtual reality or augmented reality environments to give improved perceptions of reality with the additional sensation of touch. This type of haptic enhanced interface can provide a sense of reality in different domains, such as 3D painting, brush-based models,

calligraphy, dentistry, or training and learning in different subject fields (Perry et al. 2017; Shenoy and Shenoy 2013). There are a number of studies on the learning effectiveness of haptic systems which report how a greater sense of immersion in a learning environment can promote deep conceptual learning for difficult concepts. Haptic feedback can assist the development of fine motor skill performance in dentistry (Perry et al. 2017) and in other medical areas.

Shaikh and his colleagues proved their students' improved conceptual understanding with haptic-enabled learning experiences (Shaikh et al. 2017). An adjunct simulator with haptic feedback was used to develop the clinical skill of nasogastric tube placement from patient's nostril to the stomach for feeding or drainage. This proved an effective method of education and training for nursing students and medical students (Chiang et al. 2017).

Calligraphy is another area where the haptic interface has been tried, since Chinese calligraphy needs a unique way of controlling the strength of strokes. Force feedback may enhance the achievement of a different type of learners. It may be more beneficial to kinesthetic learners with this preference of the visual, aural, reading/writing, or kinesthetic (VARK) sensory modalities. A Chinese calligraphy system and its effectiveness with children and adults were examined (Narita and Matsumaru 2015).

Earlier research reported that haptic guidance also improves learning outcomes related to handwriting motor skills. New findings were additionally reported that performance was significantly improved whether it was with full or partial haptic guidance (Teranishi et al. 2017).

As technology develops, various new learning resources with haptic feedback, in particular, become available for use. The Learning Anatomy with Haptic Feedback System (LAHFS) is one such new resource. It was developed to give haptic feedback from virtual organs in human anatomy classes (Yeom et al. 2013). This relatively new resource may help learners access anatomical specimens outside limited clinical settings, thus expanding study opportunities (Chuttur 2009; Craig et al. 2010).

It is interesting to investigate what factors influence student acceptance of such a novel resource, if there are any. For example, how a learner reacts may vary according to their gender, preferred learning style, or previous experience with a similar type of resource. Students of different genders may accept different models and media differently. Other considerations include olfactory and video media, the effect of multisensory of visual and tactile modalities, gender differences in learning style preferences among undergraduate physiology students, and many more.

Multimodal deep learning has improved achievement compared to unimodal learning (AlKhasawneh 2013). To understand the preferred sensory modality of students for learning anatomy, consenting students were administered a printed form of version 7.2 of the VARK questionnaire. The VARK instrument is only one of many to measure student learning styles or preferences (Coffield et al. 2004), and some have questioned the value of learning styles. However, opportunities to assess kinesthetic learning in higher education are rare, and the main research question was to measure the level of acceptance of the haptic device as a tool.

Haptic sensory learning resources for dental learning or surgical training have been used (Ullrich and Kuhlen 2012) with 79% of students benefiting from the study as kinesthetic learners. This led us to investigate if the haptic sensory learning resource would have a similar effect in anatomy learning, at least for kinesthetic learners.

Problem-based learning (PBL) can be used with the different learning styles (Almigbal 2015) to investigate the learning outcome according to the preferred learning styles of learners.

Design Research Paradigm

The design research paradigm is one of common approaches for collecting data from users in a cyclic manner. This cyclic approach is useful to find an appropriate model and users' acceptance of a system through different versions at different

stages. The design research paradigm was adopted to assess acceptance of the haptic-anatomy system. The Learning Anatomy with Haptic Feedback System (LAHFS) was developed using the software development life cycle over three stages (Fig. 1). The system evolved as the user tests were performed in a cyclic manner.

The technology acceptance model (TAM) (Davis et al. 1989) was the basis for the acceptance questionnaire. TAM posits that usage of technology is influenced by perceived usefulness and ease of use (Chuttur 2009; Marangunić and Granić 2015).

Later, variant branches came out of the original technology acceptance model from Fred Davis, leading to the theory of reasonable action (TRA) and the theory of planned behavior (TPB) with many extensions or modifications in the technology acceptance field. Haptic enabling technology and TAM is another branch of TRA/TPB focusing more with haptic technology (Oh and Yoon 2014).

Ease of use and usefulness were the two important factors used to measure if the users will accept the system in this TAM-based study. TAM used a few questions to collect the data. These two main elements are used to measure the acceptance of technology by users. Each element of acceptance was measured based on ease of use and usefulness; then the acceptance was analyzed with respect to other variables such as gender, prior experience, personal preferred learning styles, and their enrolled courses.

For this project, data was gathered from participants in three distinct ways. A postexperience survey using a visual analogue scale (the "VAS questions") was administered to each participant to gather their perceptions of the haptic device linked to the 3D display. This survey provided much of the information required by the TAM theory. The focus to discuss here is how the system was accepted, based on student gender, preferred learning style, and their prior experiences with any similar sort of interface. The main questions to measure the users' acceptance were "was it easy to use the system?", "was the system useful?", and "would you recommend the system to the university to adopt?" as they are three important points from TAM. A visual analogue scale

Indications for Kinesthetic Learning Through Haptic Devices, Fig. 1 LAHFS (a) starting, (b) rotating and disassembling, (c) floating option of other menus, e.g., quizzes

(a)

(b)

(c)

(VAS) was used in the survey to measure the level of agreement to a statement between 0 and 100. The second method of gathering data was through optional quizzes which participants could choose to activate during their LAHFS session. These quizzes gave feedback on anatomical learning achievement and comprised pop-up randomized questions with randomized answers. Finally, the VARK questionnaire was also administered to some users after the LAHFS session to identify the learning modality they most preferred.

The haptic-anatomy system was developed with the Phantom Omni (Yeom et al. 2013). A force-feedback pen was gripped by the user, who saw anatomical organs on a screen to learn to identify human internal organs and associated medical nomenclature (Yeom et al. 2013). When any part of each organ was held and moved around, it allowed the user to examine the selected organ with 360° of perspective (Fig. 2). Also, the user felt different haptic feedback depending on the hardness/rigidity and texture of the organ. Thus, pushing into a liver met gentle resistance, but tapping a rib encountered very hard opposition. The three development versions were tested by three different user groups.

The user groups were from 3 different cohorts with 89 participants including 58 males and 31 females with average age of 20 years old as the system developed further at each cycle according to the design research paradigm. The courses that the users were enrolled in were mainly Bachelor of Medicine/Bachelor of Surgery (MBBS), Bachelor of Education (Health and Physical Education and Outdoor Education), Bachelor of Exercise Science, and Bachelor of Human Movement. Bachelor of Computing students participated in user test.

The first user test was done with second-year students, but the other two user tests were done with first-year students. Hence our assumption was made that no preknowledge was present. The VAS survey questions asked if the user performed well with the system, if the system was useful, if it was easy to use, if the user was physically stressed or mentally stressed, if the user would recommend the school to adopt the system as a learning resource, and if the optional quiz was useful.

Analysis of Preferred Learning Style

The VARK questionnaire was used to find out each participant's preferred learning style(s) out of different available measurements. Some researchers argued about the validity of learning styles, yet many students believe the conventional wisdom that learning styles are legitimate and adopt it outside of class study.

The VARK model classifies learners based on the sensory modality in which they prefer to have information presented to them. The individual categories are: Visual (V): if learners prefer (prefer or absorb information more effectively when it is presented in a visual form. Auditory (A): if learners prefer to hear information being presented to them such as attending classes, discussing the materials with others, and reading notes or text out loud. Reading/Writing (R): learners prefer to see new information in writing via text or tables. Kinesthetic (K): learners prefer new information to be clearly relevant to the real world or something that they can manipulate with their hands. Hands-on practices and real-life examples are recommended. Also, this model categorizes the learner as bimodal, trimodal, or quadrimodal depending on how many preferences each student has.

As assessed by the VARK questionnaire, further information was sought if their preferred learning modality had any influence on their ratings of the LAHFS system, system version 3. Participants' responses were correlated to the VAS questions and their learning achievement quiz results with their scores on the VARK questionnaire.

The percentage of visual (V), aural (A), read/write (R), and kinesthetic (K) options chosen out of the total number of options selected was based on a relatively small population of the study. The percentages of different options by each participant were V 23% $\pm$ 10 (24%), A 25% $\pm$ 12 (24%), R 22% $\pm$ 9 (21%), and K 29% $\pm$ 13 (28%), with all approximately normally distributed among $n = 43$ system v3 participants who completed the VARK questionnaire (Shapiro-Wilk tests of normality $p = 0.078$ to 0.288). These percentages are similar to those reported

Indications for Kinesthetic Learning Through Haptic Devices, Fig. 2 (a) User environment, (b) system structure

on the VARK website, based on 74,932 respondents from January to March 2015, V 21.7%, A 24.6%, R 24.9%, and K 28.8%, as well as for those in medical fields (13,181 respondents), V

22.0%, A 24.3%, R 24.9%, and K 28.8% (Oh and Yoon 2014).
Pearson's correlations (r) of percentage V, A, R, and K with the five VAS questions are shown in

Indications for Kinesthetic Learning Through Haptic Devices, Table 1 Correlations $r > 0.1^{(1)}$ and $r < -0.1^{(2)}$

	Performed well	System useful	Easy to use	Mentally stressed	Physically stressed
V %	-0.005	0.131 ⁽¹⁾	-0.021	-0.098	-0.041
A %	-0.151 ⁽²⁾	-0.173 ⁽²⁾	-0.115 ⁽²⁾	-0.008	-0.111 ⁽²⁾
R %	-0.123 ⁽²⁾	0.037	-0.005	-0.039	-0.024
K %	0.232 ⁽¹⁾	0.027	0.127 ⁽¹⁾	0.114 ⁽¹⁾	0.149 ⁽¹⁾

Indications for Kinesthetic Learning Through Haptic Devices, Table 2 Correlations $r > 0.1^{(1)}$ and $r < -0.1^{(2)}$

	Would recommend	Quiz useful	Quiz result
V %	0.018	0.197 ⁽¹⁾	-0.107 ⁽²⁾
A %	-0.163 ⁽²⁾	-0.272 ⁽²⁾	-0.103 ⁽²⁾
R %	0.010	-0.100 ⁽²⁾	-0.015
K %	0.128 ⁽¹⁾	0.165 ⁽¹⁾	0.194 ⁽¹⁾

Table 1. None of these correlations were statistically significant. Interestingly, only “kinesthetic” positively correlated with performed well ($p = 0.135$) and easy to use ($p = 0.418$) but also with mentally stressed ($p = 0.468$) and physically stressed ($p = 0.339$).

Table 1 presents correlations (Pearson’s r) between VARK learning style percentages and VAS questions.

Similarly, there were weak positive but nonsignificant correlations of “kinesthetic” with “would recommend to university,” “quiz useful,” and quiz results ($p = 0.413$, 0.290 , and 0.217 , respectively). “Visual” learners also weakly but nonsignificantly positively correlated with finding the “system useful” and “quiz useful” ($p = 0.403$ and 0.214 , respectively).

Table 2 presents correlations (Pearson’s r) between VARK learning style percentages and VAS questions as well as quiz results.

One of the most popular areas of applying the haptic technique is in training or learning fields or with simulations.

A randomly generated quiz from the question bank was attempted by each student. When their answer was incorrect, they were given another chance to answer the question. This was because j holding the pen and trying the different system may impact performance, although each user spent about 10–15 min with the haptic learning modules beforehand.

The optional achievement quizzes were used by 46 students in total. The test size was small, but

the results indicated the interface was easy enough to be adopted (or easy to use). The mean quiz results from students of each of the different learning modalities were V (58.75%), A (66.36%), R (82.50%), K (80.71), and multi with K (65%). Thus, visual learners did not achieve greatly with the system, but read/writing and kinesthetic learners performed well.

Previous 3D Experience

Quite a number of students identified themselves as having prior experience with 3D interfaces ($n = 63$), whereas very few users had used haptic interfaces before ($n = 15$). Users with prior experience of 3D interfaces were more likely to assess the system positively (Fig. 3). The item, “would you recommend,” was significantly different as $p = 0.025$ from t-test between two groups with and without previous 3D interface experience. The post-activity quiz score gave $p = 0.050$ with Mann-Whitney U test, showing another significant difference. Therefore, the study concluded previous experience with a 3D interface made users more likely to accept the haptic learning resource.

Conclusion

In such an important and difficult subject as anatomy, a new type of learning resource could well

Indications for Kinesthetic Learning Through Haptic Devices, Fig. 3 Responses with/without prior 3D experiences

help students. The availability of different resources, including a haptic system, can assist students who learn differently.

No significant difference was found in learning achievement between students with different learning styles. This means the haptic system works for all different styles of learners; at the same time, it doesn't have any particular benefit to kinesthetic learners.

However, significant differences were found with prior users of 3D models. They assessed the system as "performed well." Their quiz results were higher than for students without previous 3D experiences. When users had previous experiences with 3D systems, they gave more positive responses and achieved higher quiz results; however, these experienced users found the system more physically stressful. One thing to clarify was if the users were talking about the same level of 3D experience. Most of them were talking about 3D images of games and other applications, unlike 3D models which can be manipulated in the LAHFS system.

Gender differences were not found in this experiment, unlike most of the literature. This could mean that the haptic system is gender neutral. However, the population for comparison was rather small (under 100 students).

More recently, this result has been independently confirmed and reported, showing that conceptual knowledge showed significant knowledge gains, but there were no significant differences

between the haptic and non-haptic condition (VARK Learn Limited 2016).

Simulations are being developed with skin mechanisms and tactile nerve fibers to fill the gap of current systems to convey sensory information with multiple fingers (Saal et al. 2017).

Also, various tactile-haptic methods are being trialed to enhance accuracy in learning, for example, with shape recognition, basic piano education, or surgical training (Lee et al. 2017; Pinzon et al. 2017; Pala and Mihci Turker 2019).

In a future, the system will let students explore each anatomical object with their whole hand rather than just a single haptic touch point. This will be more natural for users and will incorporate tactile (touch sensations) as well as force feedback. As haptic technology develops rapidly, such new devices will add to the kinesthetic learning experience of the haptic-anatomy system (Webb et al. 2019).

Introduction

The use of information and communication technologies (ICT) in education has, for a while now, generated extensive interest as well as being attributed to have an important role in education. Therefore, the introduction of ICTs in education is no longer a new concept, at least in industrialized and developing countries. However, the path

taken by those that decide to introduce ICTs in education vary and so does the reasoning. Chile's journey was in itself unique given that prior to 1990, Chile had minimal exposure to ICTs in education, that is, no massification of ICTs in primary and secondary levels of education. There was of course, well before the 1990s, a limited exposure to computers at higher education levels. In fact, since 1968, courses were offered by the four main universities in computer programming. On the other hand, at the business level, computers had made a limited presence. However, for a short period in the early 1970s, the government approved a novel cybernetic project that was to be short lived as a result of a military *coup d'état*. With the return of democracy, the newly elected government was interested in making changes to an ailing education sector and the need for reform was palpable.

The newly elected government had identified that Chile's education system had structural deficiencies, poor performance results, impoverished schools, and lacking in quality and equity. Thus, ICTs were seen as tools that would enrich the students' education and ultimately provide a better quality of education under a more egalitarian system. The broader reforms were centered on the regulatory frameworks, changes to curriculum (to both, primary and secondary levels), teacher training and development, increasing pedagogical resources and infrastructure for schools, improving students' attendance, and increasing the time spent on teaching. However, the introduction of ICTs into the education system and the reforms has not been without challenges and/or criticism.

This journey of reforms started in 1992 with the birth of "Programa Enlaces" or "Enlaces" for short. A pilot program that was meant to interconnect a small number of schools in the capital Santiago and which later expanded to include the region of Araucania located about 650 km to the south of Santiago.

Enlaces was primarily an educational web that connected schools and provided access to ICTs. But Enlaces expanded quickly and by 1995, over 5000 schools had been connected. By the year 2000, Enlaces was further expanded and managed to connect the totality of rural schools in the

country. Enlaces was also enhanced by other initiatives that placed more ICTs in the classroom, introduced teacher training in the use of ICTS, connected rural school with improved bandwidth, increased the number of student scholarships that provided free laptops or computers, and the creation of educational software and portals. To this day, new programs have been spawned from within Enlaces such as the “Me Conecto para Aprender” program created in 2015, which is still operational and that gives all year seven student enrolled in public schools, a free personal computer.

Preamble to Massification and a Novel Project of Cybernetics

Computers had entered the Chilean business environment as early as May 1961 when the first IBM-1401 was acquired to be used by Customs in the port city of Valparaíso, followed by the Treasury, the Air Force, and a mining company some years later (Ojeda et al. 2019). By then, universities had become aware of the use of computers and so between 1963 and 1966, the main universities at the time had acquired computers, namely, the Catholic University, Santa María University, and the University of Concepción obtained IBM-1620 computers (Ojeda et al. 2019). Also, between this period in 1964, the State Technical University (nowadays, known as Universidad de Santiago de Chile or USACH for short) receives as a donation a Datatron computer (Ojeda et al. 2019). Throughout this period, computers, which required a sizeable capital outlay, space, and know-how, were mainly the domain of big business, government bodies, and some universities. However, during Allende’s government, which lasted from 1970 to 1973, there was a bigger vision on how computers could be used, and in 1971, the government started to develop a cybernetic system for the management and transference of information (Ojeda et al. 2019). The project had been approved by the President and was known as Cybersyn (Ojeda et al. 2019). It was envisaged that Cybersyn would enable real-time economic information on the state-owned enterprises

(Espinosa and Walker 2011; Ojeda et al. 2019; Pickering 2004). In charge of the project was Fernando Flores, who had been appointed as the technical director of the state development corporation known as CORFO and who was aware of the solutions and theories of the British Stafford Beer, known for his work on *management cybernetics* and the Viable System Model (VSM) (Ojeda et al. 2019; Pickering 2004). Management cybernetics is best described as:

the concrete application of natural cybernetic laws to all type of organisations and institutions created by human beings and to interactions with and within them. (Cwarel Isaf Institute 1989, online)

Beer’s VSM was a diagnostic tool that enabled the studying of organizations while focusing resources and relationships required to support an organization’s viability rather than concentrating on its formal structure (Espejo et al. 1999; Pickering 2004).

Beer was invited to Chile to help in the design and implementation of a control system that would comprise and model the entire economy (Espinosa and Walker 2011; Ojeda et al. 2019) and in the short time, from 1971 to 1973 (Ojeda et al. 2019; Pickering 2004) that the project Cybersyn was in its inception phase, it succeeded in modelling the whole of the social economy, including the design of performance indicators, developing of the necessary information systems and decision-making means (Espinosa and Walker 2011). However, the project came to an abrupt end when the military coup led by Pinochet deposed President Allende on September 11, 1973, and so, it was the end of one of the most advanced cybernetic and political projects of its time (Espinosa and Walker 2011; Ojeda et al. 2019; Pickering 2004) and one can only speculate where it would have led to in terms of its purpose, possible expansion, demand for trained personnel, and the education sector both as an adopter and or enabler.

Return to Democracy and the Birth of Enlaces

Mr. Patricio Alwyn became the first president of Chile after the Pinochet dictatorship had ended

and democracy was once again restored (Bauer 2017), Mr. Alwyn's presidency spanned from 1990 to 1994. Prior to 1990, Chile had no public policy to promote the massification and use of ICTs in education and its exposure in this area was rather limited (Jara 2013). Although, there was a small number of schools which either had computers or a lab, these were mainly secondary schools where the aim was to teach programming, for example, languages such as Basic or Logo (Jara 2013). At the academic level, Jara (2013) indicates that there was an incipient and interested community on this theme. However, in March 1990, a program known in Spanish as the "Programa de Mejoramiento de la Calidad y Equidad de la Educación Básica" (usually referred to as "MECE Basica") was conceived (Jara 2013; Toro 2010) and would later have an impact on how ICTs were perceived, which led to a massification of ICTs in schools.

The new authorities recognized that changes were necessary in the education system due to the failures of the inherited system which had been through a period of decentralization and privatization during the Pinochet dictatorship (Planas 2011; Sánchez et al. 2011; Toro 2014, 2018). There was also a consensus that as a result of the challenges posed by the *how-to*, *to form*, *to educate*, and *to learn* in a world where information is the central element of productivity, where individual and collective opportunities are played out within the networks that are accessible (Bellei 2010). Thus, President Alwyn's newly elected government wanted to respond to these challenges and so, the year 1992 saw the creation of "Programa Enlaces," often referred to "Red Enlaces" or only as "Enlaces" ("Linkages Program" in English). The project was born within the MECE Basica initiative (Claro et al. 2012; Enlaces 2019c; Sánchez and Salinas 2008; Silva and Figueroa 2002; Toro and Tatnall 2016; Toro 2010).

With finance and advice from the World Bank, the initiative got underway in 1992 connecting 12 schools in the capital, Santiago then expanding to Araucania, some 600 km to the south of capital

and covering 100 schools in this region (Colaboradores de Wikipedia 2019; Enlaces 2019c). And so, the country embarked on a national initiative to create a national educational network of primary and secondary schools with the objectives of introducing ICTs in schools, enriching the curriculum, giving students equal opportunities to access ICTs (Enlaces 2019c), in short, to improve quality, equity, and efficiency (Holm-Nielsen et al. 2004). Thus, as argued by Bellei (2010), Enlaces is a public policy in which the government has been the promoter of technical innovation, ultimately getting the new generations closer to ICTs (Bellei 2010).

The "Enlaces" program was developed as an experimental initiative to implement computer technology in schools (Claro et al. 2012; Sánchez and Salinas 2008). The inception of Enlaces was not straight forward as the then Minister of Education, Mr. Ricardo Lagos had to contend with two main approaches, each with their pros and cons (Toro 2010). One approach intended to follow a similar path as taken by Costa Rica, with emphasis on the learning of specific programming languages and requiring massification which would require a high number of computers installed throughout the country (Jara 2013; Toro 2010). According to Toro (2010), this approach was met with questions on acceptance, adoption, quantifiable result, and obsolescence. Notwithstanding, this was a highly visible approach politically, but it was not adopted. Therefore, a second proposition was considered, one that was much less visible politically, but which has been in the long term generally seen as a public policy in which the state has been the biggest promoter of technological innovation (Bellei 2010). The second option was Enlaces, a pilot program with a much smaller presence and that would lay the foundations for a much bigger future project (Jara 2013). The year 1992 also saw the creation of a software program known as "La Plaza" (in English, town square) which was developed to facilitate the use of the computers by teachers and students alike using the metaphor of the town square as a meeting place (Enlaces 2019c).

The Road to Introducing ICTs in Chile's Schools

In 1993, Enlaces was primarily involved in making the program widely visible by holding expos throughout the length of the county whereby, teachers and students presented samples of their successful adoption and use of ICTs in the curriculum.

Enlaces expanded quickly and defying expectations, by 1995 a total of 5300 schools (ranging from primary to secondary levels) had been connected and that also included Easter Island and Antarctica (Enlaces 2019f). This meant that about 2.5 million students from primary to high school had access to ICT resources provided by Enlaces (Enlaces 2019f). However, the majority of rural schools had to wait another 5 years to start connecting to Enlaces (Jara 2013, Enlaces 2019g). The same year, a web site was created under the domain of “enlaces.cl” that used the Mosaic browser and which contained educational material (Enlaces 2019f).

In 1996, an alliance was formed between the Ministry of Education and the universities along the entire county (Enlaces 2019b), and this was known as the “Red de Asistencia Técnica de Enlaces” but usually referred by its initials as RATE (Enlaces 2019b; Jara 2013). The aim of RATE was to support the primary and secondary school that were part or pending connection to Enlaces, becoming an integral component to the expansion of Enlaces throughout the country (Toro 2010; Jara 2013). Initially, this alliance comprised 6 universities and later expanded to 24, out of which, 7 had a leading role in the implementation of Enlaces to the rest of the schools in the country (Jara 2013). The universities which were part of RATE were involved in providing the school teachers with ICT training, as well as, technical support, email services, and to keep up with the growing demand due to the rapid expansion, the universities also organized a network of about 1000 trainers who were usually school teachers who originated from the schools already connected and who served as Enlaces’

coordinators who helped to create a nexus between the school and university frameworks (Hinojosa et al. 2009; Toro 2010; Jara 2013; Enlaces 2019b).

In 1998, the educational reform officially incorporated Information Technology as a curriculum subject for high schools (Enlaces 2019h). Also, for 4 consecutive years, that is, 1998, 1999, 2000, and 2001, CDs containing educational resources and tools such as software, catalogues, and search engines were distributed to schools (Enlaces 2019h). Most importantly, the Internet arrives free of charge to the schools with the help of private enterprises such as Telefonica CTC Chile with connecting speeds of 64 kbps (Enlaces 2019h).

The year 1999 saw the creation of a manual which was provided to all schools and that intended to support the learning of the Internet and its services and to assist in the incorporation of the Internet as a pedagogical tool (Enlaces 2019i). Information technology is in its second year as a subject in high schools.

The year 2000 marks an important point for Enlaces due to its expansion of coverage which would connect rural and remote schools (Enlaces 2019g; Hinojosa et al. 2009); the same year, a catalogue of educational software was created to increase and provide newer educational tools (Enlaces 2019g). This was followed in 2001 by the creation of the Portal EducarChile to complement the other resources already available (Enlaces 2019j; Oteiza and Miranda 2010). At the same time, more software was developed. This time, it was designed to complement the teaching and learning of language and communication (Enlaces 2019j).

In 2002, Enlaces is recognized with an equity award at the Second Information Technology in Education (SITE) conference held in Nashville, USA, for increasing the digital equity and the renovation of education through the use of ICTs (Enlaces 2019k). During this period, teachers were also situated at the vanguard of the integration process (Enlaces 2019k). However, the government also pushed to increase and or bring

digital alphabetization to the wider population and so, those schools that had computer labs would open them to enable the training of those who wished to take part from the local community (Enlaces 2019k).

During 2003 and 2004, there were further resources made available such as digital classes, refurbished computers placed in classrooms (approximately 30 students per computer), improving the performance in Mathematics using ICTs, but most importantly, a study conducted by the “Universidad Catolica” University concluded that a significant number of teachers were using ICTs and it also indicated that 90% of teachers were using the internet to access educational resources such the EducarChile portal, more than twice a week (Enlaces 2019l). The rest of 2004 saw a further rollout of Internet access to remote rural schools (Enlaces 2019l).

In 2005, the Ministry of Education creates the Enlaces Centre of Education and Technology as recognition that technologies could provide a tangible support role in the school learning process (Enlaces 2019m). Moreover, the Centre’s objective was to be a point of reference and initiator of public policy related to educational technology and the digital alphabetization of the general population (Enlaces 2019m). During this period, a system of certification was introduced so that students could prove their competency in ICTs (Enlaces 2019m). The year 2005 also saw the creation Edulinux, this was a Linux-based solution that provided an alternative open source that extended the life of some obsolete computers and improved access to the Internet, email, and other educational resources (Enlaces 2019m). Finally, this year, Enlaces also co-funds broadband access to schools with the aim of improving connectivity (Enlaces 2019m).

In 2006, Enlaces and the United Nations’ Development Programme (UNDP) reviewed a document which dealt with human development and technologies, specially the section dealing with ICTs in education (Enlaces 2019n), the document reiterated that the school had become a focal point to diminish the digital breach for it

was in the school where the students had free access ICTs (Enlaces 2019n).

In 2007, the Government starts implementing the Technologies for Quality Education plan or in Spanish “Plan Tecnologías para una Educación de Calidad” or TEC for short (Enlaces 2019o; Toro 2010). According to Toro (2010), the objective of the plan is to improve the quality of education through the opportunities afforded by ICTs as well as incrementing the existing equipment, and within a period of 3 years (from 2007 to 2010), over 209,000 new computing equipment were delivered (Donoso 2010). The plan was aimed at the preschool, basic, and secondary levels of education (Enlaces 2019o) and was based on three central pillars, namely, infrastructure, teacher’s digital competency, and a new generation of digital educational resources (Toro 2010). The plan had a budget for an investment of US\$200 millions on infrastructure (Enlaces 2019o).

According to Enlaces (2019p) and Donoso (2010) in May 2008, the government implemented a new initiative, and this was known as the “Laboratorios Computacionales Moviles” which was in fact comprised of mobile computer labs and aimed at third year basic education students (Enlaces 2019p). These mobile labs were equipped with a portable computer for the teacher and sufficient similar computers for the students, including Wi-Fi connection (Donoso 2010; Enlaces 2019p). The objective of this initiative was to facilitate a more incorporated approach between teachers and students and technology in which a 1:1 student per computer setting was possible (Donoso 2010; Enlaces 2019p). According to Donoso (2010), the success of this initiative was notorious by the fact that there was a reduction in the number of students per computers, getting it closer to that of developed countries, that is, 1 computer per 9.8 students. Whereas, 4 years earlier, it was possible to have 1 computer per 30 students Donoso (2010).

The year 2009 was a period in which an additionally 21,568 practicing teachers were trained in the use of ICTs and by 2010, a further 20,000 newly graduated teachers were also trained (Donoso (2010). Moreover, during the course of

this year, Enlaces launched the first catalogue of educational digital resources in Latin America (Enlaces 2019q) under the name of “Catálogo de Recursos Educativos Digitales” or referred to as RED for short (de Saint Pierre 2010; Enlaces 2019q). Also, Enlaces (2019q) indicates that during this time, the first national census on educational technology was conducted, and it included municipal schools, subsidized schools, and a small sample of private schools. The collected information related to the infrastructure in the schools, access and use of ICTs by students, teachers, principals, and coordinators (Enlaces 2019q). Finally, Enlaces (2019q) indicates that the result of the census created the Digital Development School Index or in Spanish “Índice de Desarrollo Digital Escolar” (IDDE for short). The index revealed the level of development, the state of the infrastructure, the capabilities of the different human actors, and the management and use of the technology in the schools. During this time, President Michelle Bachelet established a scholarship that was designed to benefit students who were recognized as lacking resources or from a low socioeconomic status and who at the time were enrolled in a public or subsidized school. The scholarship was labelled as the “I Choose my PC” or in Spanish, “Yo Elijo Mi PC” (Toro 2018). As a result, 30,000 PCs were given to those students that met the criteria in the first year of the scholarship and then increased to 60,000 per year (Junta Nacional de Auxilio Escolar y Becas 2017; Colaboradores de Wikipedia 2017). According to figures provided by Junta Nacional de Auxilio Escolar y Becas (2017), since its inception, 350,000 students have benefited as a result of the scholarships and an extra 30,000 who are enrolled in a subsidized school in grade 7 are expected to benefit in 2017. In 2019, the scholarship is continuing, offering students in year 7 of public schools a choice of portable computers, ranging from an Acer Aspire 1 – Intel Pentium 5000 N, HP Stream – Intel Celeron 4100, LENOVO Idea PAD 330 – Intel Pentium 4415 U (Ministerio de Educación 2019b).

In 2010, Enlaces obtained the ISO 9901-2008 quality certification for its Evaluation of Digital Educational Process (Enlaces 2019r). The

scholarship “Yo Elijo Mi PC” continues to benefit students (Toro 2018).

The year 2011 was again another year during which new initiatives were created; more equipment was handed out and evaluations were carried out with the aim on finding out where, what, and how improvements could be made (Enlaces 2019s). It was the first time that the SIMCE test was used to measure the capabilities attained in ICT learning (Enlaces 2019s). The SIMCE which is the abbreviation for “Sistema de Medición de la Calidad de la Educación,” (in English it translates to “Measurement System for the Quality of Education”) and to this day, it is still in operation. The SIMCE is managed and run by the “Agencia de Calidad de la Educación” (in English, “Agency for the Quality of Education”), which was established by Law Article 20.529 and which is tasked to safeguard and monitor the quality of education (Agencia de Calidad de la Educación 2017b; Biblioteca del Congreso Nacional de Chile 2017; Toro 2018). The primary aim of SIMCE is to create a series of tests devised to measure academic performance and the quality of education. These tests are administered to primary students in years 2, 4, 6, and 8, as well as those in secondary education of years 10 and 11. Accordingly, the advocates of SIMCE at the time of its inception argued that these tests would also help parents make informed decisions on the performance of schools and thus enrolling the students at the school of their choosing. It must be clarified that SIMCE was created as part of the market driven reforms that were made to the education system during the Pinochet regime and which viewed education as a marketable commodity (Bellei 2010). Presently, the results are made public and are accessible online with detailed performance results by region, locality (i.e., urban/rural), classification (i.e., private, subsidized, municipal), and by school (Agencia de Calidad de la Educación 2017a; Toro 2018). In addition, though the program “Matemática” which relied on ICTs to teach mathematics also showed that an evaluation of 2906 students in years 5 and 6 of basic education, from 25 separate schools, had demonstrated a significant improvement in maths (Enlaces 2019s).

Also, the year 2011 saw the creation of another free of charge portal where primary and secondary students were able to access content related to the national curriculum (Enlaces 2019s). The available material included videos, simulators, and animated images. In terms of equipment, 417 digital/interactive blackboards were given to a total of 99 schools including pedagogical support to those schools in the implementation and adoption during teaching (Enlaces 2019s). At the same time, 790 schools selected a total of 37,000 educational resources from the RED catalogue to support their work in the classroom (Enlaces 2019s) and 3,000 rural schools received specialist digital resources and training to be used in mixed grades classrooms (Enlaces 2019s).

During 2012, more initiatives were introduced that included the use of ICTs. One of these was known as “Mi Taller Digital” or digital workshop which consisted of extracurricular workshops that aimed to develop the capabilities necessary for the twenty-first century use of ICTs and included such themes as robotics, video games, digital comics, and video editing (Enlaces 2019t). Another initiative was the creation of a platform that included the curriculum content in English, including Mathematics so that students could reinforce their language learning (Enlaces 2019t). Currently, there are over 200,000 students taking part in this initiative (Enlaces 2019d).

The “TIC y Diversidad” (in English, ICT and Diversity) initiative was also developed which included teaching math, science, and history to students with hearing impairment; in fact, by 2014, the totality of schools catering for students with special audio needs were covered by this program (Enlaces 2019u). The coverage comprised the ICT equipment, educational resources, and the training of school personnel (Enlaces 2019u).

The use of tablets as teaching and learning tools by preschoolers was also launched (Enlaces 2019t). The approach for this initiative is set up as stations whereby the students move to and complete a series of exercises and then move to the next station to complete a different set of exercises; these can range from geometric figures, numbers, and logical exercises (Enlaces 2019t).

Finally, the second census takes place to measure the penetration and use of ICTs in schools, the first census had taken place in 2009 (Enlaces 2019t). The results of the census were published in 2013 and permitted the decision-making process around the areas of infrastructure, use, and management ICTs (Enlaces 2019t). Furthermore, the data gathered in previous years by SIMCE TIC indicated that in their ability and use of ICTs, 46.9% of students were at a proficiency level of beginners, 51.3% were at intermediate level, and 1.8 at an advanced level (Enlaces 2019u; Toro 2018). However, the census also concluded in general terms, that only a small percentage of students had met the required level of cognitive abilities necessary for the processing and generation of information (Enlaces 2019u).

In 2015, President Michelle Bachelet announced the creation of a new program by the name of “Me Conecto Para Aprender” or in English, “I Connect to Learn” (Enlaces 2019v). The program meant that all year 7 students enrolled in public education would receive a laptop and its main objectives were to further reduce the gap in access and use of ICTs, to improve the quality of education, and to support the learning of those student enrolled in a public school (Enlaces 2019v). In addition, part of this program also included pedagogical material related to the use of ICTs and was aimed at the teachers as well as the student’s family (Enlaces 2019v). As a result, Enlaces (2019v) indicates that 70,000 students benefited under this scholarship. Also, according to figures provided by Junta Nacional de Auxilio Escolar y Becas (2017), since its inception, 350,000 students have benefited as a result of the scholarships and an extra 30,000 students benefited in 2017 (Ministerio de Educación 2017), and by 2019, about 130,000 students would be able to receive a computer (Ministerio de Educación 2019a, b). However, the year 2015 also saw the creation of a pilot program which was a first for Enlaces which together with the Special Education unit (Enlaces 2019v), launched the program labelled “TIC y Retos Múltiples” (in English it would translate to “ICTs and Multiple Challenges”), and consisted in trying to define a pedagogical strategy and a set of assistive

technologies that would promote via the use of ICTs, access to communication and involvement, the development of autonomy and knowledge on students who presented multiple disabilities (Enlaces 2019v).

The following years, 2016–2018 saw the expansion of Wi-Fi connectivity, more reconditioned computers were handed out to replace obsolete models found in some schools (Enlaces 2019e), and by 2018, 40% of students attended a school with optic fiber connectivity (Enlaces 2019a). Also, continuing from workshops conducted in 2018 is the National Plan of Digital Languages 2019 which seeks to develop digital capabilities, creativity, logical thinking while learning a programming language (Enlaces 2019d).

A Measure of Success

In almost 30 years of existence, Enlaces through its many initiatives has undoubtedly been a success in terms of practically reaching universal coverage, that is, students in basic and secondary schools owning or being able to have access to ICTs in schools (Donoso 2010; Enlaces 2019p). Moreover, Enlaces has been able to diminish the digital divide that impacted disadvantaged students and to change negative perceptions by some teachers and principals on importance of ICTs in education (Hinostroza and Labbé 2010). However, there is still some work to be done towards the expansion into preschool years where access to ICTs is yet to be universal (Donoso 2010). The benefits from Enlaces have not just been experienced by the students, but teachers have also been able to access, learn, and incorporate ICTs as part of the daily teaching activities (Donoso 2010). As argued by Oteiza and Miranda (2010), Enlaces has brought about a consensus across the political spectrum on the necessity to expand the access to ICTs. In addition, Oteiza and Miranda (2010) indicate that changes in education tend to be slow and less visible in the short term and so initiatives need to be maintained for prolonged periods of time. However, the process of introducing ICTs is a

complex one and is not limited to the delivery and plugging in of some ICT equipment (Oteiza and Miranda 2010). In fact, the introduction of ICTs can be seen as a cultural change that impacts and permeates the many aspects of society such as the social, cultural, and economics dimension (Hinostroza and Labbé 2010; Oteiza and Miranda 2010; Toro 2018).

Even when from an implementation and coverage perspective, it can be argued that Enlaces has been a success (Bellei 2010), this argument can be deduced from a singular perspective whereas, while these reforms and initiatives were being implemented, the country experienced a number of protests carried out by students calling for a more equitable and affordable education as the current system still contains the vestiges of the market driven reforms from the Pinochet years (Bellei 2010; Toro 2010, 2018). Chile remains one of the most unequal of the OECD countries and performance results seem to have reached a plateau (OECD 2016, 2017a, b, 2019). However, this is no reason to scale back or terminate the Enlaces initiatives. In fact, it remains to be seen if other social initiatives coupled with further but more inclusive education reforms can bring more universal benefits in the longer term.

Synonyms

Digital technology in education; ICT in education; ICT integration; ICT pedagogical affordances

Introduction

Information and Communication Technologies (ICTs) have encroached in education systems to a degree that they have become an integral part of the educational ecosystem. Though the integration of ICT in education has been a contentious issue, there is no way to ignore it because of the pedagogical benefits in the classroom. The growing presence of various ICT applications in schools impacts teaching and learning as ICT is now fundamental in the knowledge economy and the educational ecosystem. This has resulted in new ways of learning and teaching in a complex digital environment (Bartlett-Bragg 2017). Digital technologies are widely seen as enhancing teaching and learning, thus fuelling their rapid adoption and integration in the classroom. Their rapid growth in education has resulted in the pursuit of alternative pedagogical approaches throughout developed and developing societies. ICT integration in education holds great appeal to learners as it has the potential to transform and disrupt traditional teaching practices (Blin and Munro 2008). The Oxford English Dictionary defines disrupt as “(1) disturb or interrupt and (2) seriously alter or destroy

the structure of.”¹ This work was based on the thematic analysis of many studies, including coding and categorization, which resulted in eight technology affordances constructs: responsiveness, equity, processing data, social connecting, podcasting, virtual connecting, multimodal, and integrated writing.

The presence of ICT in education has ushered in unparalleled transformation in knowledge representation and pedagogical practices and introduced new methods of communication, presentation of information, and presentation of text, unlike before where information was presented in a linear and single-media format (Díaz Andrade et al. 2017; Thapa and Hatakka 2017). According to Dlamini and Mbatha (2018) the “prevalence and adoption of Information and Communication Technology tools in education has often been guided by utopian perspectives without proper research to understand the schooling context and teachers' ICT development needs” (p. 17). This exploratory work was conducted within the constructivist perspective in an effort to contribute to the ongoing debate over whether ICT should be conceived as supporting tools or as an integral part of cognitive development.

The scope of the systematic analysis was limited to studies published between 2007 and 2017, and the focus was defined by four thematic classes specified in the Human-Computer-Human Interaction (HCHI) model (DiGiuseppe and Partosoedarso 2014) adapted from Desjardins and Bullock (2012): technical interactions, social interactions, informational interactions, and computational interactions. In each class we sought to uncover multiple perspectives and interpret them in relation to affordances and multimodality. To complement the Human-Computer-Human Interaction (HCHI) model, we engaged three generations of distance education pedagogy (Anderson and Dron 2011) to gain insights into the dimensions of ICT pedagogical affordances which signals change in the education landscape. The increase in educational technologies signals the

¹Dictionary, O. E. (2003). Oxford English Dictionary.

need for a generic framework for learning technologies. In South Africa, for instance, the government is investing heavily on computing infrastructure in schools, but the uptake is very slow and still “still grappling with issues of professional teacher development in ICT” (Dlamini and Mbatha 2018, p. 18). According to UNESCO (2003, p. 118), spending scarce resources on ICT without financing teacher development is wasteful. Beyond ICT infrastructure, educators and learners are expected to create learning objects and communicate ideas to solve problems and work collaboratively.

The pace of technology development is unbelievably fast; therefore, we must not be alarmed and instead try to keep up with the pace. Education needs should drive technology adoption and create new value in a technology-enabled education ecosystem. The potential for ICT in education is enormous as it promotes inclusion and demands an innovative approach to teaching and learning. Hartley (2007) asserted that the intersection of the teacher and education expands the horizon of the learner and the communication channels contribute to another unobtrusive social change. Building on the inclusive discourse, mobile technologies increase knowledge and information access in all sectors of the economy, and education is no exception (Aker and Mbiti 2010; Donner and Tellez 2008). Yang et al. (2011) confirm that mobile technology “provide individuals with unprecedented connectivity to information and inter-personal interaction” (p. 1). This work argues that ICT affordances contribute to teaching and learning and enhance social capital. The ICT affordances are aligned with the relational property of a three-way interaction posited by Anderson (2003a). The three-way interaction consists of students, content, and academic staff to enable greater engagement and ultimately create personalized learning experiences.

The aim of this study is to present a conceptual argument about ICT or technology affordances in the process of articulating what is known and what still needs to be understood about ICT integration in education. This entry addresses two questions relating to ICT pedagogical affordances in education:

1. What are the pedagogical ICT affordances in the process of learning?
2. What are the implications for ICT integration in education?

This work contributes to the new sustainable development goal on education for 2030 which has been set to “ensure inclusive and equitable quality education and promote lifelong learning opportunities for all.”² In developed economies, research has demonstrated some key drivers and mechanisms for improving standards in schools by making effective use of technology (National Research Council 2011; Roehrig et al. 2007; Hardman et al. 2008). Instead of teachers using ICT to change the learning experience, they replicated their passive practices with technology and thus were not able to reap the benefits of ICT affordances. Given the poor preparedness of teachers to handle the influx of ICT tools, we can easily conclude that teachers are not fit for the new demand of the twenty-first-century classroom. Yet, it could be that they have been sidelined with no ICT development opportunities mapping ICT affordances to teaching and learning.

An affordance perspective represents a relational approach to understanding how people interact with technology (Leonardi 2013). Affordances advocate focusing on relational actions that occur among people and technologies (Faraj and Azad 2013). The best example is the increased use of digital technologies as a ubiquitous productive tool and as an integral part of cognitive development. As such, our aim is to learn what other scholars and research groups have been doing with ICT in education. This is an effort to advance the discourse in the integration of ICT in teaching and learning and to disguise deep animosity to technology by teachers. Our goal is to demonstrate how putting technology in a more subservient role to that of pedagogy is misplaced. The intersection of technology and pedagogy has the potential to “reveal and develop our human creativity and responsiveness and

²<http://www.un.org/sustainabledevelopment/education/>

allow us to learn effectively and enjoyably” (Anderson and Dron 2012, p. 2). Despite the loadable benefits of inclusivity, our work explores further ICT affordances in order to make them visible to all educators and explain how they add value to learning and how they widen the context of learning. Digital technologies' ubiquitous characteristics must be more visible in order to understand how they promote active learning and enhance the classroom experience.

Education Intersecting with Digital Technology

Melton and Kendall (2012) asserted that smartphones, tablets which enable ubiquitous computing, video conferencing, and social networking are now deemed necessary tools in education. These tools have become the place where people intersect with technology; however there is a need for guided pathways to interact with information. According to Condie and Munro (2007, p.4), ICT “can support creativity, including critical thinking skills and problem solving abilities” particularly those with strong visual elements and related resources [multimedia presentation]. While critics have doubted the role of ICT in education, it is difficult to dispute learners' experience and enthusiasm to networked digital literacies. Digital literacies are inclusive of information literacy, computer literacy, network literacy, and media literacy (Bartlett-Bragg 2017, p. 16). Thus, digital fluency has become the basic skill necessary to address huge amounts of information available in digital platforms.

Though there is little evidence of disruption, the study focuses on the ICT affordances to alter the structural impediments to transformation of teaching and learning. Currently, the use of ICT in education is “sporadic, uneven, and often ‘low level’” (Selwyn 2007, p. 84). Instead of giving in to the “demands of the global economy and blindly following the unforgiving logic of contemporary flexible capitalism” (Selwyn 2007, p. 89), it is important to have a comprehensive understanding of the ICT affordances. According to Laurillard (2007, p. XV):

[...] we tend to use technology to support traditional modes of teaching – improving the quality of lecture presentations using interactive whiteboards, making lecture notes readable in PowerPoint and available online, extending the library by providing access to digital resources and libraries, recreating face-to-face tutorial discussions asynchronously online – all of them good, incremental improvements in quality and flexibility, but nowhere near being transformational.

Therefore, to experience transformation, educators must be able to map the ICT affordances to the principles of learning to democratize and enhance access to epistemology through interactivity and collaboration (Woolard 2012). The White Paper on e-Education (2004) asserted that ICT offers greater opportunities to widen access to learning, redresses inequalities, and improves the quality of teaching and learning in schools. In an effort to promote structural transformation in the classroom, there is a need to adopt new digital pedagogical approaches [transference of existing pedagogies]. ICT disrupts teaching practices in the classroom; therefore, there is demand for transformative ways to improve the current passive and content driven models of the classroom. According to Redmond (2011, p.1050), “ICTs offer new opportunities....” The disruptive nature of digital technologies must be embraced by educators “who in the past had not been able to do [something] themselves for lack of money or skills” and who “welcome a simple product,” which will enable them to “do more easily and effectively what they are already trying to do” (Christensen et al. 2002, p. 475). The diffusion of technologies in the classroom demands new approaches to teaching and learning in order to accommodate the diversity of learners.

The major challenge is the integration of ICT in the classroom in order to realize the potential of emerging technologies to make classrooms dynamic spaces of learning and development. According to Carlson and Gadio (2002), “Experience around the world in developing, industrialized, and information-based countries has shown that teacher training in the use and application of technology is the key determining factor for improved student performance (in terms of both knowledge acquisition and skills development

enabled by technology)" (p. 119). Despite the many benefits, ICT integration demands a systematic approach; when meaningful appropriation is realized, the resulting enrichments can be manifold.

This research entails extensive searches of relevant literature published in various education journals and proceedings from relevant conferences on ICT in education and ICT-enabled schools. The journal articles explicitly explain how ICT supports education and transform the classroom. In our search we were mindful of the quality and credibility of the articles to ensure trustworthiness, confirmability, dependability, transferability, and credibility (Lincoln and Guba 1985). In order to establish confidence in our presentation, articles from different parts of the world were engaged both from developed and developing economies to maximize the validity and reliability of the study. To further strengthen this work, we studied the authors to ensure that their credentials are impeccable, over and above the fact that the articles appeared in credible journals. According to Patton (2002), the information rich data yields "insights and in-depth understanding rather than empirical generalizations" (p. 230). In order to make credible claims, we performed an in-depth analysis to ensure information rich analysis (Patton 2002, p.40). This was to substantiate any claims made in the study. The strength of the approach was that the articles reviewed provided multiple perspectives on ICT applications in schools and how they impacted teaching and learning. The journal articles were written by credible researchers who are experts in the educational technology field and came from different parts of the world. The inclusiveness of the literature dissuades any credibility questions that may arise.

Conceptualizing Affordances

Digital technologies have become a highly valuable resource in education and are deemed necessary tools in education (DiGiuseppe and Partosoedarso 2014; Melton and Kendall 2012). Without a doubt learners in schools are exposed to

a variety of digital devices and applications. Therefore, it is important to have a deeper understanding of technology affordances and how they contribute to teaching and learning. The term affordance was first coined by Gibson, and then McGrenere and Ho (2000) expanded Gibson's definition to cover both usability and usefulness. In our case, affordances are considered in relation to human computer interfacing (HCI) as applicable in education and in connection with the opportunities that technologies bring into teaching and learning (Hammond and Manfra 2009; Hammond 2011). While ICT tools are perceived as useful education tools that support learning activities, we want to unearth the features of technology that support pedagogical activities.

The affordance perspective was popularized in design and human-computer interaction research by Norman (1988), who defined affordances as the design aspect of an object. This definition argues that the nature of an object informs how it should be used. However, subsequent scholars argued that affordances can emerge through direct interaction with technologies, which often leads to processes of experimentation and adaptation that shape the actions people take with technologies (Leonardi 2011; Evans, Pearce, Vitak & Treem 2016). Gibson's theory of affordances proposes that "The affordances of the environment are what it offers the animal, what it provides or furnishes, either for good or ill" (Thapa and Hatakka 2017). The potential value of technology affordances in education is most relevant in the large classrooms and contemporary teaching and learning environments.

Many researchers cited Gibson's definition of *affordances*, yet there was little consistency in the application of the term among these papers, and hence there is no agreement on a conceptual definition of affordances (Parchoma 2014). From the users' perspective, the relational ontology suggests that affordances emerge in practice in a particular context (Canole and Dyke 2016). In this work, we present a detailed account of ICT in education and how ICT affordances enable educators and learners to achieve cognitive development. To help bring a systematic approach, we will present an account of how technology

enhances education in general and then move on to the specifics through Vygotskian's perspective of teaching and learning. We look at the interaction between educators and content, learners and content, as well as educators and learners (Anderson 2003a). In Anderson (2003a) the three-way interaction consists of students, content, and academic staff. Furthermore, we argue against the notion that affordances exist independent of the user.

Mapping ICT Affordances to Four Principles of Learning

Governments invest a lot of money on ICT initiatives; however the uptake is disappointing given the well-documented ICT affordances to create learner-centered environments. Therefore, the provisioning of ICT infrastructure must not be construed as automatically affording learners attainment because there is intrinsically nothing in the provisioning of ICT tools that automatically guarantees cognitive development. There is a disappointing slow uptake of ICT in education even though high investments have been made to improve ICT access. There is a gap between schools' access to ICT and teachers' readiness to pedagogically integrate ICT tools into teaching. It should be noted that the demands of transformation of the classroom are real and beyond the rhetoric and the hype around emerging digital technologies.

The First Principle of Learning: Autonomy

ICT has the potential to promote and encourage ubiquitous learning which supports the learner-centered approach. ICT's transformative nature stresses the use of ICT as a lever for instructional change (Vanderlinde and van Braak 2010). Christensen et al. (2008) argues that, "the data suggest that by 2019, about 50 percent of high school courses will be delivered online." With this in mind, educators must prepare to meet this challenge with an open mind and look to disruptions

that may be taking place in the present for guidance in preparing for the future. The twenty-first century challenges many educators to rethink what they teach and how they teach (McLoughlin and Lee 2008). Given the affordances of ICT resources and their influence on teaching and learning, it is important to adopt technology-driven pedagogy that supports interactivity and learner-centered classroom environment.

The Second Principle of Learning: Connectedness

The best approach that supports digital pedagogy seems to be connectivism is known to be aligned with the digital age and network society. There is a strong belief that through simulations and gamification high-order thinking skills are developed (Clarke and Clarke 2009). However, digital fluency is key to realizing the full potential of ICT affordances especially continuous interaction with subject content, concepts and terminologies. Wang et al. (2012) define digital fluency as the ability to reformulate knowledge to express oneself creatively and appropriately using digital technologies. Furthermore, Lai (2011) asserted that the potential benefits of digital technologies depends on its capacity to support interactivity.

The Third Principle of Learning: Diversity

Digital technology expands access, collaboration, and affordability to education. South Africa is confronted with an unprecedented unequal access to quality education, particularly in rural communities or under-resourced communities; there are crucial issues that have not been adequately addressed such as teachers' preparedness to teach in the contemporary and diverse classrooms. These technologies have the potential to enrich interactions and enhance engagement with content (Canole and Dyke 2016). Digital platforms provide environments to share content and present content in multiple forms (Canole et al. 2016). However, research shows that the "pedagogical

and technical expertise of the teacher is absolutely critical” for the integration of ICT into teaching and learning (Hennessy, Harrison and Wamakote, 2010, p. 40). The potential for digital technologies to transform teaching and learning is great as long as they are used as a pedagogical tool to present content in multiple formats.

The Fourth Principle of Learning: Openness

Klopfer and Squire (2008) says that technology can have a reciprocal relationship with teaching. The emergence of new technologies pushes educators to understand and leverage these technologies for classroom use; at the same time, the on-the-ground implementation of these technologies in the classroom will directly impact how these technologies continue to take shape. Undoubtedly, without these technologies such as digital games and digital interactive activities in the classroom, strong lessons can still be achieved, but there is a sharp disconnect between the way students are taught in school and the way the outside world approaches socialization, meaning-making, and accomplishment.

Dimensionality of ICT Affordances in Education

Consistent with ICT affordances' attributes in producing various forms of social interaction and changing ways that learners engage with content and educators engage with learners, we present the dimensions of ICT affordances. These dimensions are presented through the Human-Computer-Human Interaction (HCHI) model [technical interactions, social interactions, informational interactions, and computational interactions] lens, complemented by the three-way interaction posited by Anderson (2003a) consisting of learners, content, and educators. In order to present meaningful understanding, we propose three questions: (1) What are the essential characteristics of ICT that can transform instruction delivery in the classroom? (2) In what ways are digital technologies enabling teachers and

learners to bridge knowledge gap? (3) How does ICT contribute toward the development of twenty-first-century skills [conceptualizing, abstraction, generalization, problem-solving, and information processing (Cassim 2010, p. 1)]? To explicate the concept of ICT affordances and make them useful in education, we present various interactions supported by digital technologies. In this section we are interested in capturing how ICT affordances support the principles of learning: autonomy, connectedness, diversity, and openness.

We consider ICT affordances as process concepts; thus this work is an effort to operationalize and bring meaningful linkage between pedagogical choices and technology affordances. There is value in having deeper understanding of digital technologies categories and the link to digital technologies affordances in order to develop a systematic approach to integration in education. This has the potential to enable educators to adopt and use technology in teaching and encourage a different perception toward digital technologies. According to McGrenere and Ho (2000), affordances have three fundamental properties (p. 1):

- An affordance exists relative to the action capabilities of a particular actor.
- The existence of an affordance is independent of the actor's ability to perceive it.
- An affordance does not change as the needs and goals of the actor change.

In each class we sought to uncover multiple perspectives and interpret them in relation to affordances and multimodality. To complement the Human-Computer-Human Interaction (HCHI) model, we engaged three generations of distance education pedagogy (Anderson and Dron 2011) to gain insights into the dimensions of ICT pedagogical affordances which signals change to the education landscape. Table 1 demonstrates how ICT affordances support the Human-Computer-Human Interaction (HCHI) model and contribute to clarifying the confusion surrounding technological affordances in education. The key is to manage both conceptual and technical

Information and Communication Technologies' Pedagogical Affordances in Education, Table 1 Linking digital technologies categories with digital technologies affordances

Human-Computer-Human Interaction (HCHI) model (Desjardins 2005)	HCHI model description. (DiGiuseppe and Partosoedarso 2014) Adapted from (Desjardins and Bullock 2012)	Digital technologies categories	Digital technologies affordances	References
Technical interaction (TI)	Employ basic devices and applications; create/edit documents/multimedia (p. 340)	Hardware technologies Mobile devices	Interaction between humans and machines Editing documents Principles of learning: autonomy, connectedness, diversity, and openness	(Asoodar et al. 2016; Bamanger and Alhassan 2015; Isaacs 2012; Yang et al. 2011; Zevenbergen and Lerman 2008)
Social interaction (SI)	Communicate via email, video, text, audio; use social networking systems (p. 340)	Discourse facilitation Virtual environments Virtual realities Video Texting Audio Social media Web-based Content management systems	Multiple representation Active participation Sharing of Information and Ideas Social networks Collaboration eLearning Multimodal interaction ePresence Visualization Collaborative game problem-solving Interactive learning environment Principles of learning: autonomy, connectedness, diversity, and openness	(August et al. 2016; Squire 2008, 2011; Campbell and Martin 2010; Fetaji et al. 2007; Slay et al. 2008; Zevenbergen and Lerman 2008)
Informational interaction (II)	Search for and exchange articles, video, music, books, etc. (p. 340)	Learning management system Smart glasses Databases Content management systems	Sharing of information and ideas Multimodal interaction Searching for articles Principles of learning: autonomy, connectedness, diversity, and openness	(Canole and Dyke 2016; Campbell and Martin 2010; Slay et al. 2008)
Computational interaction (CI)	Create concept maps, plans, diagrams, pictorials, graphics; process data (p. 340)	Learning management system Content management systems	Connectivity Multimodal interaction Learning analytics Complex calculations Principles of learning: autonomy, connectedness, diversity, and openness	(Campbell and Martin 2010; Digregorio and Sobel-Lojeski 2010; Slay et al. 2008; Zevenbergen and Lerman 2008)

characteristics in order to design, develop, and implement innovative ways in the classroom to realize distributed understandings. These technologies provide innovative ways to move learners

from a passive approach to higher levels of conception and analytical capabilities (Dabbagh et al. 2015; Josephson 2013). Educators' ability to integrate technology in the classroom affords them

the opportunity to pursue alternate pedagogical approaches through various interactions.

These alternative pedagogies are informed by ICT affordances enriched by Vygotsky's approaches to learning at social and individual level. Further, they extend access to learning through a vast range of diverse experiences. "ICT allows us to create, collect, store and use knowledge and information; it enables us to connect with people and resources all over the world, to collaborate in the creation of knowledge and to distribute and benefit from knowledge products" (Tondeur et al. 2011, p.152). In Table 1 there is clear evidence that ICT affordances give teaching and learning new discoveries whereby text can be presented in a variety of formats such as audio, video, and animations and support both synchronous and asynchronous communication. The ubiquitous properties in digital technologies allow learning without boundaries, continuous experimentation, and active experiential learning. ICT has a significant role to play in information sharing, social mobilization, visual representation, education, digital footprints, and instructional delivery (Dlamini 2015). According to Kuriya et al. (draft), ICT "provides multi-platform opportunities for dissemination and interaction with information" (p. 6). The effectiveness of technology affordances can be summed up according to the following constructs to ensure that they serve their purpose and add value in education:

- **Responsiveness** [increased interaction – Educator-Content, Learner-Content, and Educator-Learner]
- **Equity** [equitable access to information, real-time interaction, and flow of information]
- **Processing Data** [data analytics for intelligent insight and spatial issues affecting cognitive activities]
- **Social Connecting** [allow continuous peer-to-peer connection to interact beyond the physical classrooms and continuous flow of information]
- **Podcasting** [digital audio recording to increase interaction with content knowledge]
- **Virtual Connecting** [virtual experimentation to develop deeper understanding of concepts]
- **Multimodal** [multiple representation of text, knowledge, learning objects, etc.]
- **Integrated Writing** [used of multimedia applications and screen-based technology to support word processing and discover useful information to enhance writing]

Table 2 indicates the technology affordances constructs being supported by the literature as we continue to develop deeper understanding of the role of technology in education. The use of technology in schools remains uneven across classrooms. This could be attributed to ICT competency level of educators in a school and also the priorities of the political vision. In this article we have unearth and organize some of the technology affordances with potential to revolutionize the classroom. Asoodar et al. (2016) stated that "podcasting can be a complement to the class material" (p. 876). An analysis of findings conducted to a group of 200 first-level students confirmed that students prefer podcasts than their textbooks and notes (Asoodar et al. 2016; Evans 2008). The rapid growth of mobile devices could be significant in this discourse as they allow individuals to access content continuous, anywhere and anytime.

Bamanger and Alhassan (2015) averred that "mobile digital technology devices such as MP3 players, iPods, iPads, and smart mobile phones could offer their users the opportunity to access information almost anywhere, at any preferred time and at their own pace" (p. 63). With such advancement in digital devices and technologies, the limitations of the classroom are eliminated. The demand of the contemporary learners is "convenient learning"; therefore the ubiquity of technology provides learners with that flexibility and allows them to engage with materials beyond the face-to-face lectures. Given that podcasts for an example are in audio format enhance acquisition of knowledge and literacy development (McKinney et al. 2009; Kurtz et al. 2007). Today, we witness the unprecedented growth of interactive whiteboards (IWBs) in the classrooms, which is considered one of the most revolutionary instructional technologies that facilitate learning in different ways (Türel and Johnson 2012; Campbell

Information and Communication Technologies' Pedagogical Affordances in Education, Table 2 Literature supporting technology affordances constructs

and Martin 2010; Digregorio and Sobel-Lojeski 2010).

Türel and Johnson (2012) confirmed that IWBs enhance the functionality of existing technologies by adding interactivity and “increase students’ attention, motivation, participation, and collaboration” (p. 381). The functionality of IWBs have positive effect on learning as content is represented in multiple ways and various media can be used to accommodate different learning styles and enhance social interactions. The ability to record interactions, capturing of screenshots, and use of visual media is a plus (Türel 2010, 2011; Slay et al. 2008). These functionalities have pedagogical implications for educators to transform their pedagogy into more student-centered and interactive learning. Despite the diversity of the studies, notably the majority of the research presented in Table 2 supports the technology affordances constructs. There is also alignment with various interactions in the Human-Computer-Human Interaction (HCHI) model (Desjardins 2004) and the three-way interaction posited by Anderson (2003a).

Discussion and Future Issues

We engaged with digital technologies categories and linked them with technology affordances to develop deeper understanding of how they afford unique opportunities to learning. These technological affordances were conceptualized around their diverse potential relationship with education. We then present six constructs of ICT affordances with conceptual descriptions to allow scholars in the field to further conduct empirical research on this constructs. These constructs have practical implications for the teaching profession and practice. We hope this entry will encourage further empirical studies on ICT affordances in education to gain deeper understanding and improve adoption and appropriation in the classroom. In the literature there is no doubt about the role of ICT in education and is clear that there is a belief that it can enhance learning (Livingstone 2012). According to Livingstone (2012), ICTs “bridge forms of knowledge and literacy, and they

intersect places of learning—home, school, work and community” (p. 10). DiGiuseppe and Partosoedarso (2014) confirm that computer-based applications and digital devices enable ubiquitous learning.

The use of computer-oriented communication has the potential in collaborative learning especially through the use digital technologies such as videos, animations, images, etc. However in order to experience such affordance, there must be meaningful interactions between learning environments and learning objects. These technologies can also be used beyond the learning environments especially in teaching practice whereby digital platforms can be developed and used to share knowledge and teaching materials. This will also allow pre-service teachers to share their experiences and reflect on their teaching within a supportive teaching and learning community. Boud et al. (1993) defines learning as a holistic activity that needs to connect with people’s life experiences. The fact that digital technologies are ubiquitous in nature guarantees that individuals can access information and learning resources beyond the physical book and in the process connect, share, and collaborate in virtual environments. According to Pegrum (2014), mobile devices “represent a return to embodiment, augmenting our brains and our senses as we interact with the world around us” (p. 3). Therefore, the possibilities of ICT in education are enormous given their ubiquitous property and the transformation of space and time.

The adoption and appropriation of digital technologies in schools could push the frontiers of innovation as educators collaborate and share knowledge in virtual spaces. We are mindful of affordability especially in our context, though mobile technology has been described as the technology of choice in Africa (Pegrum 2014). Accessing equal and quality education has been a challenge in developing nations; thus the potential of digital technology to expand access to education is great. Table 2 provides a clear picture of how digital technologies can enable teaching and learning. For example, South Africa is confronted with unprecedented unequal access to quality education, especially in rural and under-

resourced communities. There are crucial issues that have not been adequately addressed such as teachers' preparedness to teach in the contemporary classroom and massive youth unemployment. Therefore in order to create opportunities to alleviate such problems, there must be investment in digital education platforms to help the country reconfigure professional and cognitive development initiatives to address the endemic challenges.

ICT affordances unlock the education space allowing the development of virtual communities and multi-representation of learning objects. Thus educators and learners access a broad array of education enrichment activities to complement their regular school curricular activities. Teachers will also have the opportunity to continuously develop their subject knowledge via the virtual community learning centers. This is to ensure that teachers have content knowledge at the appropriate level to eradicate underperformance which is attributed to the socioeconomic status of communities they serve. Digital learning platforms integrated with smart technologies has the ability to monitor learners' knowledge development in real time and provide continuous feedback on their knowledge level. This is particularly true for schools, where efforts are being made to bridge formal and informal learning.

According to Jagušt et al. (2018), "70–80% of learning takes place outside of the formal learning environment and happens spontaneously and unintentionally, in the so called informal context." Virtual and social networks have a role to play given that the out-of-class learning is the dominant way of knowledge building. However, scoping this conceptual presentation of affordances and linking them with cognitive development through empirical work remain. The evidence to support the eloquent claims being made is crucial as politicians and governments grapple with the claim that ICT enhances teaching and learning. Empirical work in this area will have a profound impact on ICT adoption and appropriation in an effort to transform pedagogy to meet the demands of the twenty-first-century classroom. This can result in Just-In-Time solutions to the disruptive nature of digital devices in the classroom and the

effort to construct social constructivist environment.

Implications and Conclusion

The intention of this work was to present technology affordance and their potential value in education. In Tables 1 and 2, we presented snapshots of how ICT affordances suit a diverse range of learners that coexists in a classroom. We organized the ICT pedagogical affordances according to four key principles for learning, autonomy, connectedness, diversity, and openness, and further present technology affordances construct based on our reviewing of the literature. It is evident that technology has the potential to transform pedagogy of personalization giving students the choice of what, when, and how they engage with education resources for cognitive development. Although the majority of the research presented in Table 2 supports the technology affordances constructs, there are different points of view. These points of view provide a more nuanced picture of the research activities and can help further inform the design of future empirical studies. At the same time, it became clear that empirical work to support the eloquent claims being made in the literature needs to be part of the research activities in education. The empirical work investigated the effects of various Technology Affordances Constructs to gain additional insights on how they impact learning and emotional engagement with text. In addition, we performed an analysis of the unique perspectives on digital technologies and how they support cognitive development at various levels of ability and competencies.

Introduction

Technology plays an important role in teaching, learning, and assessment in schools and higher education institutions. The use of computers in assessing learning is becoming widespread in

educational institutions. Assessment and learning are viewed as integral to each other; therefore, computer-based assessment – assessment using information and communication technologies (ICT) – or e-assessment is a tool that is sought to help in bringing about pedagogical change and improve teaching and learning (OECD 2010). The use of online technology in assessment has increased in recent years. This included the entire assessment process, from designing assignments, such as online assignments, quizzes, homework, and examinations, to storing the results with the help of ICT (Fluck et al. 2009). Computer-based interactive simulations have also been reported to be used in assessing students' performance (Neumann et al. 2010). Computer-assisted formative and summative assessment is being used in higher education institutes for assessing students in various subjects, especially for those with learning difficulties and special needs (Perkin et al. 2007). E-assessment is expected to enhance the implementation of e-learning and help in making it considered as much more than a textbook on screen (Weippl 2007). It is sought to provide solutions to some of the challenges for e-learning, in particular through the support of learners through formative assessment and detailed feedback. Assessing various cognitive levels using ICT, as well as improving problem-solving and higher-order thinking skills, was reported by Nirmalakhandan (2007).

E-assessment Types and Tools

Many types of e-assessment tools and tasks have been reported in the literature (Stodberg 2012) such as closed questions (multiple-choice questions (MCQs), matching, and true and false), open-ended questions (short answer and essay type), portfolios, product designs (computer programs, prototypes, and artifacts), and discussion blogs. Various IT assessment tools can be used in the classroom, including computer-based tests (Barncord and Wanlass 1999), interactive whiteboards (Firmin and Genesi 2012), and other various tools. E-assessment can be applied for both formative, where feedback on answers

is given to students to support their learning, and summative assessment, where a grade representing students' achievement is given as a final judgment (Naude et al. 2010). Closed questions format is the most used type of e-assessment, as its grading is reliable and secure. Digital portfolios are tools to measure higher-order thinking and social skills. They help students develop organizational abilities, showcase their talents and creative skills, follow up their progress over time, and advertise themselves. Online portfolios allow students to store their artifacts and media products, and it can be presented to a larger number of audience. E-assessment may also include pre- and posttests, diagnostic tests, and authentic or project-based learning.

Interactive whiteboards play an important role in enhancing teaching and implementation of ICT in the classrooms. It allows teachers to cover the three modes of learning: visual, auditory, and tactile (Landis 2005). Being able to save the lessons using interactive whiteboards and move your notes into other softwares allows teachers to create lessons at home and students to review their lessons anywhere after the class. It also helps special needs students, promotes interaction among students as well as between teachers and their students, and improves motivation of students (Landis 2005). Another newer form of interactive whiteboards are the portable wireless tablets, which operate in a similar way. It also allows teachers to control what is displayed on the board from a distance.

Weblogs, podcasts, and wikis are entering the classrooms, and they could facilitate assessment. They involve thought reflection, resource sharing, and peer interaction (Chen and Bonk 2008). Weblogs are websites with dated posts and comments on other visitors' posts. They offer a record of students' progress. It allows students to explore a topic in more depth and build on one another.

Formative and Summative E-assessment

Technologies of e-assessment are not seen as in themselves being inherently either formative or

summative, but rather the way we use the assessment tool determines whether it is either (Ashton et al. 2004). Formative e-assessment is an easy way of introducing technology in the assessment process in higher education institutions. Pachler et al. (2010) defined formative e-assessment as the use of ICT to support the process of gathering and analyzing students' learning and attainment of the course intended outcomes by teachers.

According to Ashton et al. (2004), computers have a role in at least four forms of assessment: diagnostic testing, self-testing, continuous assessment, and summative assessment. The first three forms are considered formative assessments. Computer-based assessment is particularly effective in formative assessment, as it provides immediate feedback, which is essential to formative assessment. Objective testing (multiple-choice questions) is normally associated with e-assessment. Other types of questions have been included in computer-based testing; however open-ended questions requiring a free text response are often absent from e-testing due to limitations in computerized assessment technology (Vardi 2012). These difficulties may be overcome as the technology improves. The integration of multimedia elements, animation, and application of random parameters and the inclusion of communication between the assessment engine and the multimedia element expand the available method of asking and answering a question and offer valuable opportunities to enhance student learning through formative assessment. More research on enhancing the validity and reliability of e-assessment, especially summative one, is expected to undergo significant change over the coming years.

Formative e-assessment helps students to reflect on their own learning (Pachler et al. 2010). Black and William (2009) proposed five key strategies for implementing successful formative e-assessment in the classroom: design effective questions and learning tasks that measure learning outcomes, provide feedback, share learning intentions and criteria of success, treat students as responsible for their own

learning, and make students learning resources for one another.

Online quizzes and assignments are widely implemented in various subjects' courses in higher education. They take different forms and are implemented in a variety of modes. Instructors choose the appropriate mode that motivates their students. Butler et al. (2008) studied the differences between online quizzes and its traditional counterparts and its effect on students' performance. Immediate feedback provided by the online assessment and the possibility of students attempting the same quiz multiple times is considered one of the main advantages of online quizzes. They also claimed that students obtained higher quiz averages; this indicates that students used immediate feedback to review before trying the quiz again. This influenced their performance and learning of the course. Hirsch and Weibel (2003) concluded that online assignments may motivate students to attempt problems and questions multiple times to give them a chance to correct their mistakes. Feedback can be more effective if it is understood by students, whether it is from a computer or humans. Moreover, instructors could use the feedback to revisit concepts where students had difficulties with while solving the assignments. Developing online quizzes and assignments is time-consuming and requires resources, but it is worthwhile and of valuable benefits.

Feedback enhances students' understanding, skills, and self-learning. In e-assessment, feedback consists of the grade achieved and specifying the questions that students answered correctly and incorrectly. Students could monitor their own learning and discover their strengths and weakness. Feedback could be from their peers and/or their instructors (Carless 2012). Electronic feedback promotes collaboration between students and exchange of ideas and also helps students to analyze their own performance and achievement and reflect on their overall work. Vardi (2012) concluded that computerized assessment with immediate written feedback and automatic marking benefits students' learning. The given feedback should have motivational nature and not too many comments and hints.

Implementation of E-assessment in the Classroom

In the classroom, e-assessment can be implemented in online as well as blended courses through stand-alone computers or networks where distance learning is required.

Various tools, softwares, and learning management systems (LMS) have been used for e-learning and e-assessment, such as Moodle, where secure and simple assessment can be conducted. According to Wheeler (2001), implementing IT in the classrooms will make some forms of assessment, such as traditional testing, redundant and unnecessary and replaced by computer-based testing.

There is sufficient evidence that using information technology (IT) in education helps in changing classroom learning environment from teacher-centered to student-centered and supports collaborative, communicative, productive, and project-centered learning environment as well (Firmin and Genesi 2012). When integrated effectively in classroom learning and assessment in combination with traditional resources and techniques, IT can provide the best classroom environment (Kennewell et al. 2008).

The way of using e-assessment in the classroom and students' experience and perceptions about it have been reported in literature (Miller 2009). Van der Pol et al. (2008) studied how students receive the online feedback from their lecturers and peers. Integration of interactive questioning and discussions into the learning environment and its impact on enhancing students' self-learning abilities have been reported (Nix and Wyllie 2009).

Students' Perspectives on E-assessment

The majority of students find e-assessment programs beneficial to their learning, according to Jiao (2015). Research showed that students see assessment as part of their learning which can be practiced by themselves or their peers (Rastgoo et al. 2010). Dermo (2009) measured the perceptions of students toward e-assessment. His study

revealed that students think positively about e-assessment. Sorensen (2013) study concluded that e-assessment engages students more, and they see it of added value. Other studies (Gotlib et al. 2015; Petrisor et al. 2016) showed that students prefer e-assessment over traditional ones.

Security and Dependability in E-assessment

Dependability includes various aspects, such as availability, reliability, safety, integrity, and maintainability. The success of electronic examination systems is influenced by other security requirement factors, such as prevention of cheating.

The extent to which an examination system is ready, available, for use is essential to holding exams, especially large-scale examinations, as sudden breakdown may occur or students might try to knock it down if they fear to fail. Holding the examinations at university test centers and using redundant hardwares were suggested by Weippl (2005) as a way of increasing availability.

Delivering a correct service and reliability, with respect to all test versions as well as grading, is essential to the success of e-assessment. Automatic grading of language responses with fair reliability has always been a challenge to e-assessment. The random selection of questions to create various exam versions has to be adjusted to make sure that all versions are reliable and have comparable levels of difficulty. If the system does not check for validity of students' answers of free text questions, we might see problems with the system, as they might write symbols the system does not recognize (Howard and LeBlanc 2002).

There are very few security risks involved when we implement e-assessment, as no harm is expected even if all data is lost. Data can always be recovered through backups.

Unauthorized users must not be able to modify the exam questions and students' answers. Data integrity is essential, so before even starting the exam it should be made sure that the questions are not altered and the students' answers will be

stored in an unaltered way. Swiderski and Snyder (2004) stressed on the importance of applying the principle of defense in depth in order to protect system access for unauthorized personnel.

The ability of the system to be modified, updated, and repaired is what we mean by maintainability. Security problems have to be handled fast, and exams have to be tested before installing them on the system.

Advantages and Disadvantages of E-assessment

According to AlSadoon (2017), some of the e-assessment advantages for students, educators, and educational institutions are allowing for evaluating important life skills, improving the quality of tests, raising reliability of grading, reducing time of marking, encouraging students' participation, giving immediate feedback, and reducing printing costs. The effect of using computer-based testing and assessment on students' achievement as compared to traditional paper-pencil ones has been reported by various studies (Chua 2012; Shuttleworth 2009; Yu and Ohlund 2010), with mixed results. Bhatti et al. (2005) concluded that students who are shy to participate in classroom discussions are more active in online ones, since it allows them to show their communication as well as higher-order thinking skills. However, e-assessment has some disadvantages as well; preparing tests is time-consuming, there are worries of dishonesty in e-test taking including illegal help during the test, and technological resources are needed (Rowe 2004). To overcome some of these problems with e-assessment, instructors could use a bank of questions so the test is different for every student, and students may be blocked from viewing their answers after completing the test.

Keys to the Success of E-assessment

Teachers need to properly be trained, supported, and provided with the necessary resources in

order to implement various types of technology in the classroom. According to Quesada-Serra et al. (2014), lecturers must be trained to enhance their competence and skills in order to be able to implement assessment in general. Effective training programs need to be implemented in order to train higher education instructors on e-assessment and learning-oriented e-assessment (Rodriguez-Gomez et al. 2016). They also measured the instructors' perceptions on the importance of the training program they provided on their e-assessment competence and skills, by implementing a mixed method research. Their research showed that instructors' skills were enhanced in assessment planning and design, monitoring of students' learning, participation of students, and improvement of the assessment process in general.

Conclusion

Using information and communication technology in assessing students' learning helps changing the classroom environment positively. E-assessment is now used in many higher education institutions across the world. There are many forms of e-assessment which have been reported in the literature. E-formative and summative assessments have been implemented widely, through various IT tools, such as interactive whiteboards, digital portfolios, tests, authentic or project-based learning, closed questions, product design, and discussion blogs. Formative e-assessment helps students to reflect on their learning. E-assessment can be implemented in online as well as blended courses. Online assignments are used in various courses and subjects in higher education. The main advantage for such tasks is the immediate feedback that students could have, as well as the possibility of students repeating the assignment many times to give them a chance to correct their mistakes. Feedback in e-assessment helps students to monitor their learning and motivates them. Training of teachers and instructors is key to the success of e-assessment implementation. Security and dependability are critical issues in

e-assessment. There are many advantages and disadvantages to be considered when we talk about e-assessment. Some of the advantages are allowing for evaluating important life skills, improving the quality of tests, raising reliability of grading, reducing time of marking, encouraging students' participation, giving immediate feedback, and reducing printing costs. However, e-assessment has some disadvantages as well; preparing tests is time-consuming, and there are worries of dishonesty in e-test taking including illegal help during the test.

Information Technology for Local Education Authorities and School Districts, Use of

Gary Cifuentes

Los Andes University, Bogotá, Colombia

Synonyms

Educational change; ICT policy plan; Policy enactment; Strategic educational management; Technology leadership

Definition

School technology leadership and strategic educational management are defined on this section as specific conditions for the successful integration of technology from a school-level perspective. When considering these conditions, it is possible to study the interaction with external authorities and organizations at local, district, and national levels. From an organizational and situational perspective, technology leadership can be defined as a distributed practice for setting the vision of ICT integration; as an institutional attribute, it refers to the allocation of conditions to foster educational innovation on different domains. On the other hand, strategic educational management refers to a participatory practice in which organizational complexity is tackled through governability, collaboration, and a shared vision.

The management of educational institutions in a globalized world presents challenges, different from those in previous decades. Therefore, an interconnected environment, supported by new technologies and different information systems that increasingly monitor schools, demands persistent communication with external groups and organizations. For this reason, school leaders and administrators must assimilate a great amount of information that has to be managed, both within and external to the institutions. Different actors with different responsibilities are also involved, and school leaders must identify them competently in their own institution. In this highly complex setting, educational leadership also depends on decision-making related to different areas such as infrastructure, curriculum, and budget. Consequently, it is important to reflect on the main concepts, dimensions, and issues linked to the work of school leaders when they interact with external authorities at a local, district, and national levels.

Part I of this entry describes leadership and educational management as fundamental school-level conditions to foster innovation within and external to an educational institution. Part II analyzes different levels of strategic management, in order to understand how school administrators

should use IT to expand possibilities for innovation beyond the boundaries of classrooms and institutions.

Part I: Leading and Managing Educational Innovation with New Technologies

In the past two decades, literature on school technology integration has focused on different dimensions such as pedagogy, teaching practices, student assessment, and criteria for technology acquisition. In this regard, scholars have devoted less attention to organizational and institutional variables that represent conditions for successful integration of technology (Goodison 2002; Hayes 2007). The community of information and communication technology (ICT) researchers can be divided into those investigating the effects of technology in student performance, those examining ICT integration from a qualitative perspective, and those focusing on conditions at an organizational or school level (Evers et al. 2009).

At the same time, the last group is divided between those focusing on a holistic perspective in order to devise overall models for ICT integration, and those examining the role of a specific condition, such as the characteristics of individual teacher, teacher attitudes toward computers, gender differences, and teacher beliefs. The underlying assumption is that pedagogies and technologies are not enough to foster innovation, as they are intertwined with organizational and institutional variables (Vanderlinde et al. 2011). Even schools with easy access to technology do not necessarily improve teaching practices, as a result of not only ICT teacher competencies but also school-related factors (Cuban et al. 2001).

Considering this last subdivision in the community of ICT researchers, the following segment analyzes two specific conditions for successful integration of technology from a school-level perspective: school technology leadership and strategic educational management. As will be demonstrated, these conditions are necessary to study the interaction with external authorities and organizations at local, district, and national levels.

Leading Innovation with Technologies

The extensive literature on leadership developed in the twentieth century has deployed a set of traditions that are used when studying this concept in organizations. The most established classification identifies a first tradition that relates to individual traits of a single leader; the second tradition relates to leadership styles or behaviors beyond personal characteristics; the third tradition criticizes the aforementioned traditions, because they omit situational and organizational factors. As a response to these traditions, new leadership and relational theories have emerged in the field surpassing the boundaries of administration and psychology. The field of education has been based on these traditions and emerging theories, which emphasize that effective leadership improves learning and institutions (Leithwood et al. 2004).

Scholars assert that successful leadership is related to external interaction with groups, as it will be emphasized in this section: “Much of the success of district and school leaders in building high-performance organizations depends on how well these leaders interact with the larger social and organizational context in which they find themselves” (Leithwood et al. 2004, p. 24). Drawing on empirical research and from an organizational perspective, three practices are identified for achieving successful leadership: setting direction, developing staff, and redesigning the organization (Leithwood et al. 2004; Leithwood and Jantzi 2005).

Following this perspective, some scholars refer to ICT leadership as the practice of setting the vision of ICT integration, fostering ICT teacher development, and providing conditions for access, support, and policies for change within the institutions (Dexter et al. 2002; Zhao and Frank 2003).

Some scholars consider this kind of leadership as the key role of a single individual appointed within an institution. The school leader (Granger et al. 2002), or the ICT coordinator (Tondeur et al. 2008), is responsible for the successful integration of technology. Other approaches refer to the concept of technology leadership as an institutional attribute rather than focusing on an individual. In

this regard, Anderson and Dexter (2000) describe some features at this institutional level:

- An appointed ICT committee (an organized team that has the responsibility for planning, implementing, and evaluating technology integration)
- A financial plan for ICT integration
- The allocation of time for planning ICT integration by the principal
- Economic support from the government
- A concrete ICT teacher-training program

All of these features and practices can be analyzed separately to understand technology integration from an organizational perspective. However, some scholars have preferred to study the complex interaction between these practices and artifacts related to the process of leading innovation through ICT. Related to this, the recent literature refers to the concept of ICT policy plan, a blueprint that shows how an institution integrating ICT for education might look (Fishman and Zhang 2003). Indeed, having a shared vision of ICT integration and an ICT policy plan are key factors that researchers identify as conditions for successful integration at the school level (Hew and Brush 2007). As ICT policy plans can exist on different scales (national, district, or school levels), it is necessary to highlight the alignment and the interaction of the institutional plan on the district and the national levels.

As a very complex artifact, an ICT policy plan embeds different areas or policy domains, including vision development, infrastructure, curricular integration, budget, and teacher training. According to Vanderlinde et al. (2012), what they refer to as ICT leadership is the complex interaction between an ICT policy plan and the leader’s effort to formulate and implement this artifact.

An appropriated ICT policy plan should be based on a complete diagnosis of internal needs and requirements of different areas (infrastructure, curricular integration, teacher training, etc.) aligning a vision and goals to those needs and requirements. Therefore, ICT policy planning

refers to the process of enacting such a plan through different strategies and interactions:

ICT policy planning is a process of developing, revising and implementing ICT plans in order to guide organizations toward broader goals ... situated within Fishman and Zhang's (2003) deeper definition of ICT policy planning ... is defined as a comprehensive school document containing a variety of strategic and operational elements concerning the integration of ICT in teaching and learning (van Braak 2003; Frazier and Bailey 2004). (Vanderlinde et al. 2011, p. 1340)

In this regard, one could say that both the product (ICT policy plan) and the process (ICT policy planning) are fundamental to technology leadership and successful integration. Overall, any attempt to interact with external authorities and organizations implies ICT policy planning, considering the five policy domains described in Vanderlinde et al. (2011):

- ICT vision development
- Financial ICT policy
- Infrastructure ICT policy
- ICT continuing professional development policy
- ICT curriculum policy

Put differently, a school's vision should not be isolated from the external demands of parents, local communities, the job market, etc. Infrastructure should be planned according to key allies and stakeholders in the region that could sponsor institutional improvements. Teacher professional development should be aligned with national guidelines and regulations that school leaders should be aware of. As stated above, school technology leadership, or ICT leadership, implies an effort from a leader and her team to foster innovation through the enactment of all these different domains, an endeavor that necessarily includes external cooperation and negotiation.

Strategic Management for Technology Integration

Typically, leadership and management have been studied as related concepts, even as interchangeable synonyms. For instance, some scholars refer

to change management as an attempt to combine these two concepts (Brown 2013). Conversely, others differentiate leadership as encompassing educational change at different levels, whereas management is linked to the administration of resources of a different nature. The following describes educational management as a second school-level condition for the successful integration of technology, highlighting the complex interrelationship with leadership for educational innovation.

Management of education has usually been linked to administrative issues covering areas such as budget and staffing. Even the reference to the management of technology in educational settings implies the formulation of a financial plan for the acquisition of technology or provision of technical support for the institutional platform. Given the complexity of educational institutions, it is nevertheless important to surpass this simple concept.

Strategic management represents a turning point in the traditional approach of school administration, as it existed in education in the past century (UNESCO 2000). This implied that leading an educational institution was an administrative endeavor. Traditional school administration also assumed a labor division in which directors led the institution technically, whereas teachers were in charge of curricular and instructional practices. This led to the fragmentation of activities and the lack of a shared vision. On this model, the administration was related to teaching (not learning), achieving goals that came from the outside (top-down rationale), causing a lack of interest in the community in pedagogical matters. Indeed, a final result was the separation of administrative activities and pedagogy as two different realms.

Compared with the school administration model, strategic educational management considers pedagogy as the center. As a participatory-oriented model, it focuses on coping with organizational complexity, uncertainty, and conflict, promoting innovation through collaboration. Strategic educational management is related to governability, which is a way to integrate the technical and political aspects of education.

Beyond technical and external “recipes” for general problem solving as previous approaches to educational administration, school leaders have to consider their own particular context; hence, strategic management has to do with governing collectively, inspired by a shared vision and considering the interdependence of actors within and external to the institution (UNESCO 2000).

In general, technology leadership and educational management are usually linked to the internal reality of an educational institution. However, it is important to understand that both dimensions also operate outside the institution. As stated above, technology leadership and educational management imply that school leaders foster innovation from a strategic perspective that involves key actors and alliances from inside as well as outside the institution. In other words, there is no way to strategically lead and manage innovation for change using IT unless a strong collaboration with external groups and organizations is considered. In the following, different forms of strategic management will be considered in relation to ICT policy planning.

Part II: Levels and Conditions for External Interaction

In this segment, different levels and conditions are analyzed as keys to leading and managing IT integration for educational purposes. As will be demonstrated, technology is highlighted as a means and an end. As a means, technology can support communication processes to establish fluent interactions with different actors at each level. As an end, technology is a matter of leadership and management fostering innovation within educational institutions. Three different levels can be distinguished when considering the strategic management that a school leader has to deal with.

Depending on the political and administrative organization from each country, the levels can be named differently. So, the first level of interaction is the *local*. It embeds permanent communication with the mayor’s office, parents, and other actors

that benefit from the educational institution. The second level is the *district*. In some countries, this level is also considered as zones or departments; in other settings, it can be provinces composed of municipalities. The third level is the *national* that, once again, will be considered differently if there is a federal or centralized administration in a particular country.

These three levels encompass different and complex relationships with the public and private sectors. Put differently, external relationships will be different if an institution receives subvention from the private sector based on its geographical location. Conversely, a municipality that has to share public funds among all educational institutions will establish a different set of relationships and competition for budget.

So, it is also important to make different statements when considering if a school belongs to the public or private educational system. The level of autonomy must be considered. In other words, autonomy can vary if an institution depends on national or district resources from the government, or if an institution that depends on tuition fees, because it is private.

An additional contextual factor is the type of educational institution. Different types of institutions encompass particular visions with specific educational goals. For instance, some institutions offer technical training to develop specific competencies for the job market. Other institutions offer a more traditional or classical education, based on general competencies that guarantee access to tertiary education. For instance, in the curricular domain of these two types of institutions, leading and managing technology integration will be substantially different based on their educational vision and goals.

Considering the previous conditions, three types of strategic educational management can be identified when considering the integration of technology. As stated above, these types of management are related to ICT policy planning, whose purpose is to enact a vision of how education can be fostered when integrating technology. In fact, these types are closely linked to the different domains embedded in an ICT policy plan (ICT vision development, financial ICT policy,

infrastructure ICT policy, ICT continuing professional development policy, and ICT curriculum policy). The following highlights the external relationships for the domains at the local, district, and national levels:

Financial management. Considers the allocation of budget for the acquisition of products and services declared in the ICT policy plan. Although it is difficult to declare a priori the key areas for investment, because it depends on the institutional diagnosis and the identification of needs, the most common areas regarding technology integration are devices and Internet supplies. Nevertheless, strategic management should also link teacher training to the financial plan, because it increases a successful integration of technologies for enhancing teaching and learning. A key practice for leaders is the involvement in the call for bids from both the government and the private sectors, because they are opportunities to sustain educational innovation initiatives. School leaders should seek external guidance for building their institutional budget considering that some public and private organizations offer this technical knowledge. Key questions for school leaders in this area are related to the following questions: where and how to identify the stakeholders and other key sponsors at the local and district levels? What kind of government grants can support the financial plan? Is there a chance to collaborate with other institutions for acquisition of technology at a low cost from the private sector?

Infrastructure management. Refers to the acquisition of technology, facilities, and conditions for technology integration, such as Internet services and supplies. As a rule of thumb, infrastructure acquisition will not be successful unless technical support is included in the ICT policy plan. Put differently, the investment in technology and facilities has to be planned for the long term, given that obsolescence and user interaction must be considered when planning and managing technology in the institution. School leaders, then, should find a first key

interaction on the national level with the ministries of education, communication, or technologies (depending on the country). Locally, the communication with the mayor's office is pivotal, because many authoritative regulations are on behalf of this actor. A school leader should guarantee that an institutional diagnosis includes a precise analysis of infrastructure requirements, involving as many staff as possible (once again, in a participatory fashion), and base his leadership on questions such as the following: what kind of technological devices, services, and technical support will fulfill the needs to achieve institutional goals?

Curricular and pedagogical management. Considering that strategic management is situated in educational institutions and considering the turning point from a school administration approach, this last type of management highlights curricular and pedagogical matters. Evidently, the ministry or department of education at the national level and the provincial and mayor's offices at the local level become critical allies for any kind of initiative on a curricular level. Integration of technology in the curriculum represents a challenge that surpasses the acquisition of devices for each classroom. Instead, professional development for teacher should include a deep analysis of instructional design across different areas of knowledge. The alignment with district or national guidelines should be included in such curricular analysis, as well as learning assessment standards. A key question for school leaders could be the following: what kind of strategic alliances can guarantee the improvement and quality of the pedagogical model?

Conclusion

This section has demonstrated that technology leadership and strategic educational management represent two key dimensions, for both successful technology integration within an institution and for the interaction with external

authorities and organizations. Although both concepts have been studied vaguely by some scholars, they were described here as two singular practices that are intertwined when considering the kind of issues that school leaders have to deal with.

Leadership has been identified in the literature as a key variable for successful performance in student learning (Leithwood et al. 2004). Nevertheless, school technology leadership, or ICT leadership, has only recently received attention by scholars as one of the conditions for successful ICT integration. The practice of interacting collaboratively with internal and external actors to enact a vision of technology integration through artifacts, such as an ICT policy plan, is only possible from a distributed approach to leadership (Vanderlinde et al. 2011). In other words, leadership is not a matter of individual charisma but the orchestration of a set of relationships that embeds persons, artifacts, and interactions on different scales.

Similarly, the emphasis in educational management has changed from an administrative approach to a strategic one, in which financial and infrastructure have to be oriented by pedagogical matters. These types of management depend on a team-oriented management that surpasses the practice of a single individual. As was demonstrated, collaborative work is necessary to establish communication with external organizations. All in all, these three types should be guided by key questions such as the following: what kind of external cooperation and alliances are more suited to the declared vision? So, school leaders should strategically identify the authorities and organizations that can act as a lever for the enactment of such an institutional vision.

Although the analysis has centered on fostering technology integration for educational purposes, it is also relevant to underscore the fact that technology itself can be used as a lever for the enhancement of leadership and management when interacting with external authorities and organizations (as stated above that IT can be the means of working with authorities and organizations, not only as an end).

A first example can be located on information system platforms for administrative purposes. Many different countries are using these sites at national and district levels to centralize information on school enrollment, student dropout, and the management of administrative and teacher staffing. Although every institution can administrate its own information system platform, nowadays it is more common for external authorities, such as ministries or departments of education, to manage these platforms in order to monitor institutional performance and administrate national or district budgets.

A second example from the academic point of view includes learning management systems (LMS), frequently used as sites for instructional and pedagogical purposes. Although the interaction between teachers and students is the most common and relevant use of these LMS, school leaders can also trace evidence of teaching and learning practices to supervise educational practices. These platforms can also be useful for pedagogic management of national standards for learning assessment or curricular alignment.

A final illustration of using technologies for interacting with external groups are institutional webpages and social networks as they represent a strategic tool for external communication and diffusion of innovations. On a local level, parents are the first target of these institutional webpages. However, for strategic promotional purposes, these tools are used increasingly by school leaders who look for potential stakeholders of different initiatives for innovation. Another strategic purpose of social networks that has also been increasingly adopted is related to establishing networks and communities of learning of different types and for different audiences (principals and teachers and the most frequent users).

Overall, IT as a means to enhance technology leadership and strategic management implies the development of digital competencies in those school leaders and their teams to integrate technology for educational purposes. Along with those competencies, this section has also demonstrated the relevance of teamwork and negotiation

as necessary to increasing interaction on the local, district, and national levels.

Summary

This section refers to the work of school leaders when they interact with external authorities at a local, district, and national levels in relation to the use of information technologies. Considering an organizational and situational perspective, the role of leaders interacting with other members in order to enact an ICT policy plan represents a key factor for successful integration of ICT. Five different policy domains embedded on this ICT policy plan explain the necessary interaction between leaders and external authorities and organizations. Put differently, a school's vision should not be isolated from the external demands of parents, local communities, the job market, and others. Following the same organizational perspective, this article defines strategic educational management as a collaborative practice able to cope with organizational complexity, uncertainty, and conflict. Different levels and conditions are analyzed as keys to leading and managing IT integration from this model. On this regard, three types of strategic educational management can be identified when considering the integration of technology: financial management, infrastructure management, and curricular and pedagogical management. By last, the article considers that technology itself can be used as a lever for the enhancement of leadership and management. In other words, IT is depicted as the means of working with authorities and organizations, not only as an end for the promotion of educational innovation.

Learning Models

The ever-lurking question that has always engaged educators is what drives students to effectively learn and excel. In their review of the literature, Zhang and Ziegler (2016) reported that although there is a plethora of cognitive, personality, and other narrower traits that contribute to student performance however, meta-analyses have always shown that personality traits that are based on the Big Five (BF) factor model (in particular openness and conscientiousness

where conscientiousness was the most powerful predictor across the secondary and tertiary levels followed by openness) contribute to the prediction of student success above and beyond intelligence. The BF are five important factors that are used to describe human personality and behavior, and it is indicated to capture most of individual's daily differences in behavioral patterns and performance in many domains (Babakhani 2014; Costa and McCrae 1992; De Feyter et al. 2012; Graham 2006; Kinga et al. 2012; Lynn 2009). They are:

- (a) Extraversion refers to the extent to which a person is sociable, talkative, lively, active, adventurous, openness to experience, creative, imaginative, and excitable (Peetsma and Van der Veen 2011). Also, extraversion reflects a tendency to like people, prefer being in large groups, and desire excitement and stimulation (Digman 1990).
- (b) Conscientious students are characterized by their orderly, un-superficial, and precise manner of working which strongly enhances performance during assessment (De Feyter et al. 2012). Conscientiousness reflects a tendency to be purposeful, organized, reliable, determined, and ambitious (Digman 1990). Thus, a person who is high in conscientiousness would make an effort to be careful, organized, responsible, and able to persist at a tedious task for a longer duration than people lower in conscientiousness.
- (c) Agreeableness is characterized by being altruistic, cooperative, and trusting (Digman 1990). Agreeableness is the extent to which a person is good-natured, helpful, trusting, and cooperative. People who score high on this dimension are empathetic, considerate, friendly, and generous. They also have an optimistic view of human nature. They tend to believe that most people are honest, decent, and trustworthy.
- (d) Neuroticism (emotional stability) refers to the extent to which a person is calm and secure. Individuals who score high on neuroticism are more likely to experience such feelings as anxiety, anger, hostile, guilt, and depressed

mood (Digman 1990). Neurotic individuals are often easily frustrated (Swinton 2010).

- (e) Students high in openness are expected to be curious about new and challenging materials and to be imaginative (Digman 1990). A person who is high in openness to experience would be a creative thinker who is independent and does not like routines, has the desire to engage and understand the world, and involves in different activities (Peetsma and Van der Veen 2011).

In a review of the literature, John and Srivastava (2001) found that the BF identifies individual differences in behavior and experience and they supported the importance of the BF taxonomy as an “integrative function” because it can represent the multifaceted systems of personality description through a common framework. A plethora of research found the BF contributing significantly in explaining individual difference with respect to academic achievement (AA) (Barbaranelli et al. 2003; Jensen-Campbell et al. 2007; John and Srivastava 2001; Lynn 2009). This is attributed to the ability of the BF to provide a common language for self-report and other ratings and can help in reducing the distance among different informants and in enhancing “interrater convergency” (Barbaranelli et al. 2003).

However, the implications here are threefold (Zhang and Ziegler 2016). Initially, the underlying processes concerning such theories are still unclear. Secondly, prior studies have mostly been conducted in Western culture, and hence, little is known about these effects in non-Western cultures. For example, the existing intercultural research indicated that Asian students perform better in school than their Western peers, especially in mathematics and science because Asian students possess higher academic motivation in that they believe in learning through effort rather than innate ability. Finally, the Big Five and its impact on performance seemed to be subject-specific, i.e., conscientiousness and neuroticism were found to be important for mathematics but extraversion to be important for language learning.

Insights from UAE University

Information about UAE’s society and culture can be drawn from (UAEInteract.com). The United Arab Emirates was established in 1971 and is a constitutional federation of seven emirates: Abu Dhabi, Dubai, Sharjah, Ajman, Umm Al-Qaiwain, Ra’s al Khaimah, and Fujairah. Despite such modernizing effects, the traditional society of the UAE is still uniquely interconnected and resilient. This is reinforced by strong family, religious and tribal ties as well as traditional values of hospitality, cooperating, and sharing. Islam is the common religion and is the base to fortify the UAE society together.

United Arab Emirates University (UAEU.ac.ae) is in Al Ain city. UAEU has nine colleges. As UAEU is a federal university, it serves all the emirates in the UAE, but in the past few year, most of the emirates had their own local and federal universities and institutions, and accordingly, the UAEU coverage started to be limited to few emirates as the research results will show below.

Big Five Personality Traits

Extraversion

Students showed overall average but interesting extraversion behavior (Table 1). Most notably Extraversion2 and Extraversion4 scored the highest in this context which indicates that students don’t like seclusion and always find new ways in order not to get bored respectively.

Such high scores as contrasted with the remaining items suggesting that such students are, on average, happily and lively, like to do activities and conservative respectively. This could suggest here that such students are passing

Innate Abilities and Learning in Higher Education, Table 1 Personality traits – extraversion

Item	Mean	Std. deviation
Extraversion4	4.10	0.868
Extraversion2	4.09	0.898
Extraversion5	3.84	1.006
Extraversion1	3.72	0.996
Extraversion3	3.59	0.998
Overall averages	3.87	0.95

their academic life with the average “extraversion” traits. One interpretation for such differences in opinion could be attributed to UAE’s culture and conservative society. This assertion is worth for further investigation in future research.

Overall, the findings suggested that students are of moderate extraversion nature.

Agreeableness

As noted in Table 2, most results were toward the higher end of the scale. Most notably, Agreeableness1, Agreeableness2, Agreeableness4, and Agreeableness5 were the highest. Toward their peers, this shows that students are more helpful during the class session, affectionate, considerate, and honest, respectively. In contrast, such students seemed to averagely like giving gifts or trusting others. This finding is worth for further investigation in future research.

Overall, the findings suggested that students are of agreeable nature.

Conscientiousness

As noted in Table 3, interestingly, Conscientiousness1, Conscientiousness2, and Conscientiousness3 scored just above the average, and Conscientiousness4 was almost close to the average. This shows that UAEU students are organized, persistent, careful, and focused, respectively.

Overall, the findings suggested that students are of average conscientiousness nature.

Neuroticism

As shown in Table 4, most results seemed to slightly negate such emotional characteristics

of neuroticism and, hence, reflect a more emotionally stable students. Neuro5 scored the highest average here, and this shows that students could moderately (slightly above average) feel guilty if they commit a slight mistake. The remaining variables had lower scores, and this indicates that UAEU female students are usually not depressed, less anxious when arguing with others, they don’t get angry, and lose their calmness easily.

Overall, the findings suggested that UAEU’s students were not of a neurotic nature.

Openness

Overall students performed above the average on this variable (Table 5). Open2, Open5, and Open6 had scored the highest which indicate that UAEU students are open to other cultures, like to learn about new things and imaginative, respectively. Students scored moderately on the remaining items (variety of experiences, independence, and creative thinking) which may point again to the above discussion about cultural perspective of such (female) students. The lower score of Open1 compared to Open5 may suggest a contrast here. This could be justified on the basis that students showed a likeness (openness) toward learning new things despite their moderate knowledge about many things. This resembles a positive

Innate Abilities and Learning in Higher Education, Table 3 Personality traits – conscientiousness

Item	Mean	Std. deviation
Conscientiousness3	3.69	1.044
Conscientiousness2	3.61	1.051
Conscientiousness1	3.50	1.182
Conscientiousness4	2.98	0.915
Overall averages	3.45	1.048

Innate Abilities and Learning in Higher Education, Table 2 Personality traits – agreeableness

Item	Mean	Std. deviation
Agreeableness5	4.44	0.764
Agreeableness4	4.25	0.905
Agreeableness2	4.11	0.899
Agreeableness1	3.90	0.943
Agreeableness3	3.77	1.070
Agreeableness6	3.37	1.059
Overall averages	3.97	0.94

Innate Abilities and Learning in Higher Education, Table 4 Personality traits – neuroticism

Item	Mean	Std. deviation
Neuro5	3.58	1.249
Neuro3	2.63	1.208
Neuro4	2.58	1.226
Neuro1	2.45	1.162
Neuro2	2.41	1.135
Overall averages	2.73	1.196

Innate Abilities and Learning in Higher Education, Table 5 Personality traits – openness

Item	Mean	Std. deviation
Open6	4.16	1.090
Open5	4.11	0.909
Open2	3.91	1.009
Open3	3.58	0.827
Open1	3.55	0.881
Open4	3.35	1.052
Overall averages	3.78	0.961

Innate Abilities and Learning in Higher Education, Table 6 Overall means of the different items

Item	Mean	Std. deviation
Agreeableness	3.97	0.94
Extraversion	3.87	0.95
Openness	3.78	0.961
Conscientiousness	3.45	1.048
Neuroticism (item worded negatively)	2.73	1.196

attitude here. Open3 indicates that students moderately understand what they take in the classroom. This calls for investigating this issue further by any future research. Spending more effort by different pedagogy stakeholders to enhance and enrich student learning inside the classroom is highly envisaged here.

Overall, the findings suggested that students are on average (based on Open1, Open2, Open3, Open4) open in nature. Finally, Table 6 shows the overall means of the different items in this article. Accordingly, it could be argued here that overall, agreeableness, extraversion, openness, and conscientiousness, respectively, were the most important strategies adopted by students. Neuroticism scored the lowest mean average, and hence, students negated being of a highly neurotic nature.

Conclusion

Table 7 summarizes the article's findings and implications and discussed next.

This entry has theoretical as well as professional contributions and contentions. At the theoretical level, we have seen how the BF personality traits have assisted in identifying the innate of CIT students. Although it was not possible to elucidate the significance of the research factors on student's success as such, the BF personality traits shed interesting insights and contrasts on students' personal traits. Findings from this entry suggested that the learning strategies of CIT student were average. The highlighted contrasting views and the dominance of most responses around the average further suggested this posture. This could be attributed to personal as well as to cultural reasons as highlighted in this entry. Many of the suggested enhancements (Table 7) could be achieved by designing programs aiming at enhancing student's learning abilities by boosting their personal innate. However, it is the cultural aspects that are more difficult to unveil and address. Cultural issues require the cooperation and collaboration of the university and the community that surrounds learning in general and the family more specifically. This is an important future research area.

At the professional level, different suggestions were made to enhance student's learning strategies in CIT (Table 7). The expected outcome of this entry will be of importance to researchers, professionals, and policymakers interested in addressing weak and strong learning abilities. This is an initial research in this area in UAE, and indeed, other researchers and universities might be interested in understanding the personal innate of their (IT or others) students. Researchers could further use the suggested factors or add to them and test their significance on their students. Professionals would capitalize on many of the implications in Table 7 to design and offer more focused training programs and workshops aimed at students and officials in universities and elsewhere. Policymakers in higher education institutions could consider many of the suggestion made in this entry to devise more focused and effective policies to enhance student learning strategies.

In discussing other limitations, the dominance of females in the sample could have biased the research results toward raising female's personal

Innate Abilities and Learning in Higher Education, Table 7 Findings and implications

#	Factor	Findings	Implications and suggestions
Big Five personality traits			
1	Extraversion	UAEU's students are of average extraversion nature	Enrich the lives of students in campus beyond learning through, e.g., engaging students in social activities, sports, behavior seminars/workshops "games," personal and teambuilding, etc. Introducing IT concepts like edutainment could further entice learning
2	Agreeableness	UAEU's students are of agreeable nature	Endorse liking and trusting of others, i.e., beyond a student's closed circle of friends. This could be boosted by introducing more teamwork tasks with members' selection being randomized. Also, virtual teams or games could also lower student guards toward others and building trust by focusing on the task not the person
3	Conscientiousness	UAEU's students are of average conscientious nature	Boosting students learning capabilities on/off campus in a way to consider their studies very seriously. This could be done through seminars and workshops. Also, using electronic calendars and organizers could help students manage their different educational tasks and deliverables, etc.
4	Neuroticism	UAEU's students are not of a neurotic nature	Encourage a spirit that rewards achievements and remedy in the case of failure (avoid punishment totally), i.e., trial and error and learning from our mistakes Conducting workshops and seminars to further build students' moral and mental well-being
5	Openness	UAEU's students are of average open nature	This falls again with the suggestions made in extraversion in enriching the students' lives even inside the classroom. In addition to group activities and in promoting student's independence, we may focus on building the student's individual capabilities by giving more individual assessments, i.e., tasks like developing a personal web page, develop a mobile (e.g., personal) smart application, assemble a computer, write a report about a trendy IT topic, etc.

innate and social and cultural behavior vis-à-vis male students. Although the representation of female students in CIT is much higher than male students, future research could increase the male contribution or introduce more complex statistical tools to look for significant differences or commonalities between female and male students. More statistical analysis could look for reliability, validity, correlations of research factors/items, and how they impact student's AA (i.e., GPA). This entry attempted to provide plausible interpretations of the survey findings, but they are inconclusive statistically, and any future research could further take this issue onboard. Such issues could be complemented with more confirmatory quantitative or qualitative research.

The Big Five factors proved their usefulness in capturing most of the important issues pertaining to the personality of CIT students. In contrast,

other researchers started to criticize the BF (Barbaranelli et al. 2003; John and Srivastava 2001; Vedel 2014) pointing to the absence of a common framework to interpret the results and the agreement on the nature and the number of dimensions needed to describe personality (Barbaranelli et al. 2003). The BF do not represent a particular theoretical perspective per se but rather were derived from analyses of the natural-language terms people use to describe themselves and others (John and Srivastava 2001). Others highlighted that personality traits are as highly relevant predictor of AA as cognitive abilities, but the importance of abilities stems from what we actually do with them (Vedel 2014). Others used the BF factors as concurrent predictors of AA and of externalizing and internalizing problematic behavior syndromes (Barbaranelli et al. 2003). Therefore, it would be interesting to extend

the power of the BF with more important strategies and attempt to investigate their importance on students' learning strategies by any future research. This would be the next phase of this project.

Introduction

The setting up of institutional repositories and learning object repositories in this digital age is part of the struggle of many higher educational institutions to achieve E-scholarship: a technology-enabled environment for the discovery, creation, and preservation of digital resources for purposes such as research, teaching, and learning. These repositories are believed to have great potential to address a number of pressing challenges of access, equity, quality, and productive scholarship in tertiary institutions.

However, while many institutions have shown the impact of growing IR content, many IRs continue to struggle to show sustained growth (Marsh 2015). Lynch recently addressed this stagnant growth by asking, “Is it important for institutions to maintain a local comprehensive record of their scholarly output through their IR?” (Lynch 2017: 127). Because most institutions routinely create intellectual content for a world of information-seeking audiences, these questions of stagnating IRs and whether or not the institution needs a local collection of its scholarly record are considered very interesting (Bull and Schultz 2017).

Chan (2004) indicates that some proponents of the open-access movement see the institutional repositories (IRs) or the open-access archive as the most cost-effective and immediate route to providing maximal access to the results of publicly funded research, thereby maximizing the potential research impact of these publications. Some research libraries see IRs as a means to expand the amount and diversity of scholarly material that is collected and preserved, thus enhancing teaching, learning, and research at the host institution and beyond (McCord 2003). Some see IRs as a way to enhance an institution's prestige or branding by showcasing its faculty's teaching and learning output (Crow 2002). On the other hand, others see IRs as an essential infrastructure for the reform of the entire enterprise of scholarly communication and publishing (Guédon 2003), while a learning object repository (LOR) is a collection of LOs having detailed information (metadata) about

them that is accessible via a network or the Internet. In addition to housing LOs, repositories can store “locations” for objects that are held elsewhere (The JORUM 2005: 11). Whichever way experts look at it, the fact remains that both institutional repositories and learning object repositories are ways of showcasing and promoting higher educational institutions’ teaching and learning output.

Institutional repositories (IRs) and learning object repositories (LORs) have increasingly been deployed in academic institutions to organize, preserve, access, and facilitate the use of digital content produced by members of their communities. Figure 1 shows the repositories’ growth over time, while Fig. 2 shows the proportion of repositories by countries worldwide. There are various definitions of IRs (e.g., Branin 2005; Crow 2002; Lynch 2003) however, for this entry adopts a broader definition which sees IRs as a higher education-based set of services offered to members of its community for the management and dissemination of digital materials created by the institution and its community members. Learning object repositories on the other hand are simply viewed as places to put digital objects. Similarly, a learning object repository is a system supporting a community working together to share and reuse

resources for learning. A central repository would be one that stores the objects for a defined community or organization. As objects can vary in number, size, and file type, it is unlikely that a single central repository would be able to collect or even physically hold all of the available learning objects in any given field (Hamilton 2001). Learning object repositories have the ability to share information and exchange records about learning objects and provide access to the objects themselves.

Figures 1 and 2 contain the proportion of repositories by countries worldwide for March and October 2018 (Saini 2018; Luther 2018). The deployment of IRs and LORs in the academic sector is an international phenomenon. Figures 1 and 2 also testify to this.

The USA maintains the highest percentage, i.e., 14.3% (3514), of the number of repositories maintained by the academic libraries in their higher education system in OpenDOAR as of March 22, 2018. This also shows the dominance of the USA over other countries for the creation and management of the IRs. The UK is the second leading country with 10.88% (136) of repositories. The UK shares 7.3% of total repositories registered on OpenDOAR also as of March 2018. However, the story changed in OpenDOAR (2018) report on the same data with now taking

Institutional Repositories Versus Learning Object Repositories, Challenges and the Way Forward for Higher Educational Institutions,
Fig. 1 Proportion of repositories by countries worldwide. (Source – Saini 2018)

Institutional Repositories Versus Learning Object Repositories, Challenges and the Way Forward for Higher Educational Institutions,

Fig. 2 Proportion of repositories by countries worldwide. (OpenDOAR 2018: 4)

the lead with 29% of the 445 repositories, followed in declining order by Peru with 10% of the 445. Surprisingly, the USA and UK that led in the March edition of the data are now conspicuously missing.

The van Westrienen and Lynch (2005) survey results reveal great diversity among IRs. In some countries, such as Germany, Norway, and the Netherlands, IRs have already become a common infrastructure in academic institutions. In Finland, IRs are just getting started; in Norway, 90% of the current IR records are for books and theses; IRs in France tend to have more articles; and Australian IRs have more primary sources data than those in other countries (Van Westrienen and Lynch 2005). Van Westrienen and Lynch also found that European IRs have been aided by national policies and other activities that promote the development of IRs. To buttress the above, JISC (2008) reports that “more and more IRs are being set up worldwide, with details of these being found in the Registry of Open Access Repositories (ROAR) or the Directory of Open Access Repositories (OpenDOAR).” Evidently, this is now confirmed with Saini (2018) and OpenDOAR data released in March and October 2018, respectively. The report by Westrienen and Lynch (2005) states further that 16 of the 19 top

UK research-led universities of the Russell Group have now set up IRs, while the SHERPA (Securing a Hybrid Environment for Research Preservation and Access) project has helped establish IRs in 20 institutions, including the universities of Oxford, Nottingham, and Edinburgh. Significant efforts were also noted in many Asian countries, e.g., Japan, China, and Taiwan, in the creation of IRs and LOR. In Taiwan, LOR is designed for teachers instead of students. Moreover, an increasing number of organizations are actively supporting the establishment of IRs, and a UK Parliamentary Committee has explicitly encouraged the creation of IRs in a select committee. Depositing work in an IR is increasingly being regarded as a way of maximizing the control exercised over how research is disseminated and accessed. With these reports and other evidence, it is now glaringly obvious that both institutional repositories and learning object repositories are in the vogue. have also observed that over the past year it has become apparent that the field of learning object repositories (LORs) is of considerable national and international interest. In the light of this, this entry examines the institutional repositories and learning object repositories in terms of their similarities and differences, the types of content found in them, the likely policy

guiding implementation, the challenges faced by higher educational institutions in setting up and implementing these repositories, and the possible way forward.

Institutional Repository

According to Crow (2002), “institutional repositories represent the logical convergence of faculty-driven, self-archiving initiatives, library dissatisfaction with the monopolistic effects of the traditional and still pervasive journal publishing system, and the availability of digital networks and publishing technologies.” Drake (2004) pointed out that repositories provide services to faculty, researchers, and administrators who want to archive research, historic, and creative materials. The open-access and open-archives movement, the need for change in scholarly communication to remove barriers to access, and the increasing awareness that universities and research institutions are losing valuable digital and print materials have begun to drive the establishment of institutional repositories. Crow (2002), in a Scholarly Publishing and Academic Resources Coalitions (SPARC) position paper, adds that IRs are digital collections capturing and preserving the intellectual output of a single or multi-university community. Crow emphasizes that repositories of an institution are important for two major reasons:

1. They are natural extensions of the academic institution’s responsibility to generate primary research, seeking to preserve and leverage its constituents’ intellectual assets.
2. They are a major component in the evolving structure of scholarly communication.

In addition, Otando (2010) identified another four. These are:

1. Enhancing and advancing the process of scholarly communication
2. Preserving the intellectual output and memory of the institutions

3. Increasing visibility of the parent institution and the profile of the researchers
4. Increasing the ranking of the institution in research and scholarship

Drake (2004) emphasizes that while the main purposes of institutional repositories are to bring together and preserve the intellectual output of a laboratory, department, university, or other entity, the incentives and commitments to change the process of scholarly communication have also began serving as strong motivators. Repositories may be limited to one field, one department, one institution, or a consortium of several institutions. However, collaboration through a consortium reduces costs for each member through resource sharing while expanding access to digital materials.

The characteristics of institutional repositories conceived by Crow (2002) include the facts that it:

- Provides a critical component in reforming the system of scholarly communication – a component that expands access to research, reasserts control over scholarship by the academy, increases competition and reduces the monopoly power of journals, and brings economic relief and heightened relevance to the institutions and libraries that support them
- Has the potential to serve as a tangible indicator of a university’s quality and to demonstrate the scientific, societal, and economic relevance of its research activities, thus increasing the institution’s visibility, status, and public value

Furthermore, Henry and Anderson (2005) add to the list of institutional repositories characteristics by indicating that:

- A repository contains *content*, deposited by the owner, the creator, or a third party.
- A repository architecture manages content as well as *metadata*.
- A repository offers a minimum set of *basic services*, e.g., put, get, search, and access control.
- A repository must be *sustainable* and *trusted*, *well-supported*, and *well-managed*.

- If an open-access repository, it must also:
 1. Provide open access to its content (notwithstanding legal constraints)
 2. Provide open access to its metadata for harvesting

Crow (2002) outlines the attributes of institutional repositories to include the fact that content is scholarly in nature and digital in format, employs self-archiving methods, has open access, and is interoperable and managed by individual academic communities and the research library.

An institutional repository contains diverse intellectual output of an institution that may include the following:

- Preprints of articles or research reports submitted for publication
- The text of journal articles accepted for publication
- Revised texts of published work with comments from academic readers
- Conference papers
- Teaching materials
- Student projects
- Doctoral theses and dissertations
- Datasets resulting from research projects
- Committee papers
- Computer software
- Works of art
- Photographs and video recordings
- Materials documenting the history of the institution or area

Drake (2004; Luther 2018; Saini 2018; Aguillo 2018) offers some examples of institutional repositories around the world; these include but are not limited to:

1. DSpace is an open-source digital repository system from the MIT Libraries and Hewlett Packard Labs and is mainly an example of archiving software (e-prints and other scholarly artifacts).
2. The University of California's eScholarship Repository (<http://repositories.cdlib.org>).
3. The developers of the Ohio State University (OSU) Knowledge Bank (<http://www.lib.ohio-state.edu/Kbinfo>).

4. **FEDORA** (Flexible Extensible Digital Object Repository Architecture) began as a DARPA- and NSF-funded research project at Cornell University.

5. **EPrints** – EPrints is often used as an institutional repository and has the largest installed base of any repository system. EPrints was developed at the University of Southampton. It provides a web interface for managing, submitting, discovering, and downloading documents.

As indicated by Luther (Fig. 3) in a study conducted in North America in 2018, most of the IR systems available today are community-developed open-source software (such as DSpace, Islandora, Samvera, etc.), which is consistent with the values and culture of institutions implementing IRs. Larger libraries with technical staff prefer to customize software, while smaller libraries depend on a service model (such as Digital Commons) that provides IR and publishing capabilities with less impact on staff requirements. Recent growth among smaller institutions favors a service model. The Directory of Open Access Repositories (DOAR) indicates that DSpace and Digital Commons (bepress) are the most widely held in North America. As the software begins to mature, libraries have access to more functionality which offers opportunities to introduce new services or consolidate platforms.

It is now clear from the examples that institutional repositories and open archives are being established worldwide. Many institutions use GNU e-print software for these projects. Other newly developed institutional repositories are CiteBase, OAI (Open Archives Initiative), BOAI (Budapest Open Access Initiative), Paracite, RCHIVESIC, AURA (Aberdeen University Research Archive), ERPANET, eDoc Archival, eBank UK, etc.

Challenges of Institutional Repositories

Many challenges have been identified in the literature confronting creation and management

Institutional Repositories Versus Learning Object Repositories, Challenges and the Way Forward for Higher Educational Institutions,

Fig 3 Common open-access software for IR.
(Source:)

Usage of Open Access Repository Software - North America, Institutional Repositories

of IR in academic institutions. Some of these challenges are identified and discussed as follows.

Policy Issues: For the IR to be effectively established, the committee in charge, in collaboration with the university administration, is expected to spearhead the enactment of OA policies. These policies shall be implemented in due course.

Required Equipment: The library in most institutions has realized the need for more computers and scanners. At the moment most of the units in universities use small scanner which is unsuitable for this kind of project. A high-connectivity scanner is needed to be ordered without further delay.

Staffing: Inadequate staffing has hampered the progress of most IR projects. There is to put an IR administrators in place in institutions to coordinate and manage the system and to assist end users with searching the repository. It is also important that a digitization specialist should be hired to serve as a knowledge expert for digital preservation issues and ICT staff for technical issues. So far these positions have not been created in most institutions. At the moment the electronic resources librarian manages the repository in most institutions while simultaneously managing

other units in the library. It is expected that the above information specialist should be involved with users based on the belief that relying totally on existing staff would be far too fragmented for the launch of this new service that needs concentrated attention. As the IR expands in scope, management, and support, resources will have to increase simultaneously.

Promotion: The adoption rate of the concept by the academics has been very low. The library must develop strategies to combat the challenge. Perhaps, as the library works with faculties who need to submit their content to an institutional repository, there is need to encourage them to retain copyright of their work or at least retain rights to publish their work electronically to increase the adoption rate.

Copyright Issues: The library plans to convince the management to mandate their funded researchers to deposit a copy of their articles in the IR. The library will consult with the legal officer to understand the institution's existing policies on copyright ownership for this is vital to the development and success of the repository. We also plan to offer presentations to academic staff and researchers on topics related to copyright and intellectual property rights in the digital age.

Full-Text Availability: Adding full-text availability needs to be addressed in the future. While much of this scholarship is available in full text through a library database, downloading these versions from a database might violate institutional licensing agreements with that vendor. When considering this, directly requesting full-text files from the authors themselves may be best, but even if they comply, many faculty members will still likely only send the publisher's final version, which may be most restricted in relation to IR use. A greater effort will need to be made to educate faculty members on why a preprint (manuscript) or postprint (post-refereeing) version of their work could be more easily added to the repository.

Limited Access: Venkadesan (2009) observed that limited access to scholarly publications is a problem. The author explained that the number of papers in the repositories should grow so that it can attract the users. Krishnamurthy (2008) identified that fund, legal framework, and technical concerns are the major barriers associated with the IRs. For example, the lack of source code for OSS used in IRs is a key challenge to the IRs. Cohen (2001) identified collection development, content organization, and online access to the printed output of researchers as challenges to the repositories. Cohen and Deborah (2007) identified problems such as platform selection, partnership with stockholders, and staffing requirements for creating institutional repositories and some other technical issues as barriers confronting IR. Similarly, Lynch (2003) added the budget crunches as another major barrier to the creation and management of the IRs.

Learning Object Repositories

Before defining learning object repositories, this entry first defines learning object. A learning object (LO) is any resource that can be used to facilitate learning and teaching that has been described using metadata. Learning objects are

self-standing, reusable, discrete pieces of content that meets an instructional objective. Learning objects may be tagged with metadata so that users can easily identify and locate specific learning objects in a web-based environment. The repositories that house such objects are known as learning object repositories (LORs). LORs are a recent technological innovation aimed at supporting, sharing, and reusing resources for teaching and learning (Margaryan et al. 2007). They are digital storage boxes that host collections of digital resources in a learning object format: i.e., resources that are designed to be integrated, aggregated, and sequenced in an efficient way to produce "units of learning" that are meaningful to learners. Resources in such repositories are collected on a personal, departmental, institutional, national, regional, or international basis (Margaryan et al. 2007). Libraries, organizations, or communities may have something about everything or everything about something, but having everything about everything is unlikely. Thus, a decentralized or "distributed" model of a learning object repository is a likely scenario (Griff et al. 2002). Instructional materials like policy guides, assignments, simulations, websites, tutorials, matrices, and other kinds of formats or media expressions are easier to find from within a contained collection.

Cebeci et al. (2008: 2) assert that "LORs play an important central role to achieve these goals with their search and retrieve components. With their metadata search(es) they facilitate the learners, teachers and developers to find appropriate objects that match their learning objective and the level of study." LORs make course selection easy and save time in helping users decide what courses are suitable for their learning purposes.

Learning object repositories offer users a large volume of resources that can be used in a number of learning scenarios and activities. This huge availability of learning materials can mislead or even hinder the users unless there is a well-thought-out guidance or assistance mechanism (Mayorga et al. 2006).

Matkin (2002) lists the characteristics of the ideal learning object repositories (LORs): These include:

Authoring/creating – Formation of a sound LOR should begin at the very beginning, i.e., at the creation of the learning object. Matkin explains that without the discipline of some minimal structure that contemplates its eventual storage and retrieval, the creative process may have a very small impact, no matter how well inspired.

Review and input control – Learning object repositories should establish standards for accepting learning objects. These standards should include peer review or some form of control over the quality of the learning object (Matkin 2002).

Intellectual property and digital rights management – LORs must address the intellectual property issues inherent in publishing material. The way intellectual property (IP) is addressed might range from a policy not to accept anything that has any property restrictions on it to a single, standard, and one-size-fits-all licensing agreement. Matkin gives example of the Connections Project at Rice University which provides contributors the choice of several licensing alternatives and restricts users according to the licensing arrangements they are willing to accept.

Modification, update, removal, and collaboration – The usefulness of LORs depends largely on how up-to-date and how easily the material within them can be modified (updated or improved) and removed. For many user communities, the ability to work collaboratively on the improvement of learning objects is important. This collaborative work requires sophisticated version control techniques and records. The essential dynamic quality of LORs is what sets them apart from content repositories, particularly those created and maintained by library professionals who are usually motivated by strong archival instincts. Matkin recommends that to be useful, obsolete or substandard material needs to be periodically removed from the repository, which means that the criteria for removal and the removal processes need to be established.

Retrieval systems – Elaborate retrieval systems for LORs have to be designed to make it easy

for users to find the elements of the repository they want. This usually means some form of authentication scheme to identify at least the user or the classification of the user and to bar access to users not qualified to use the LOR. Matkin emphasizes that good retrieval begins with a sound organization scheme for the data but also usually depends on sophisticated user interfaces designed to help the users understand the data organization and how their needs can be met. Creation of these interfaces requires knowledge of the motivation of the main body of users.

Technical infrastructure – LORs need an appropriate technical infrastructure. The hardware and software configuration, which includes elements establishing security for the system, telecommunication capabilities, continuous updates to the system, and appropriate operating and maintenance staff are essential, and they usually represent significant costs.

User information – The LOR should generate information about its users and how the materials within the LOR are being used. Gaining information about the use of the system is invaluable in understanding how the system should be changed or updated and how it should be marketed.

Community support functionality – If it is true that LORs are really serving communities of users, then LORs should provide some form of support to those communities. The ability of users to communicate with representatives of the LOR and with each other is highly desirable. However, directories of related resources, newsletters, and special web events might also serve user communities.

Scalability – Matkin (2002) argues that since learning object repositories are by their nature designed to grow, it is important that they be “scalable,” that is to say that they remain effective for higher and higher volumes of material in them, of users (including simultaneous users), and of transactions. The author indicates an important aspect of scalability is the effectiveness of the retrieval system to continue to deliver the right object to the user despite a proliferation of objects.

In summary, the attributes of institutional repositories (IRs) include the provision of critical component and the reformation of the systems for scholarly communication, serving as tangible indicators of university's quality, containing content deposited by owners, and managing, searching, controlling, and providing access to such content. Learning object repositories' attributes on the other hand include authoring and creating, review and imputing control, management of intellectual property and digital rights, modifying and updating control, removal, collaboration, and retrieval.

It is important now to state the specific benefits of both IRs and LORs to the communities they serve which include the university, repository managers, depositors, contributors, and end users. For the university, establishing an institutional repository enables a university to publicize its research and teaching programs by enabling access to the work of its staff and students. The academic work of an institution can be presented in one place rather than being just spread among hundreds of journals, thus increasing visibility and prestige. The quality of a university's academic output forms an effective advertisement for the institution, attracting external revenue streams, new faculty, and students. Deposit in a university repository can ease (for the institution and for the academic author) the administrative burden of reporting publications for research assessment and review exercises.

For the libraries, while some faculty members currently dedicate considerable time and energy to the technical aspects of delivering scholarly information, the faculty's primary role will remain as information contributors, end users, and change agents. In the long term, organizing and maintaining digital content as well as supporting faculty as information contributors and end users should remain the responsibility of the library. Libraries are best-suited to provide much of the document preparation expertise (document format control, archival standards, etc.) to help authors contribute their research to the institution's repository. Similarly, libraries can most effectively provide much of the expertise in terms of metadata tagging, authority controls,

and any other content management requirements that increase access to, and the usability of, the data itself.

To the depositor, contributors, and end users of IRs, research papers that are freely available online are on average downloaded and cited earlier and more often than those that are not. Depositing academic work in an open-access repository therefore increases the profile of an author on a worldwide basis, increasing both the dissemination and the impact of the research they undertake. Regular submission of authors' work to a repository provides authors with a central archive of their work and a record of publications to add to their CVs.

The benefits of LORs to the university presuppose that by managing its learning resources collectively, the university gains all the benefits and savings of scale, realizes the full value of learning assets and sharing and reuse of learning material, saves time and effort, and helps in building a common resource making it easy to identify new opportunities. To the individual on the other hand, it allows all participants in the learning process to have something to gain. Educators share a common store of learning resources, but can create and deliver them however they choose. The quality of teaching and training is improved because everyone has easy access to the best resources and support staff are aware that resources are securely stored and centrally managed.

Differences Between Institutional Repositories and Learning Object Repositories

There have been many writings on institutional repositories and learning object repositories, but few of them discuss or point out the differences between the two. This section considers this very important issue, which many authors have ignored. A learning object repository (LOR) is a collection of LOs having detailed information (metadata) about them that is accessible via a network or the Internet. In addition to housing LOs, repositories can store "locations" for objects

that are held elsewhere (The JORUM 2005: 11). This definition presupposes the ability to store “locations” for objects that are held elsewhere. This widens the range of the LOR’s content to include material stored on distributed servers almost anywhere on the Internet. The LOR is simply a database of LOs viewed as a warehouse of learning materials. The institutional repository (IR), on the other hand, is a concept that captures and makes available as much of the research output of an institution (e.g., a university) as possible. In the first instance, this might include material such as research papers and electronic versions of documents such as theses but may also include many of the digital assets generated by normal campus life, such as administrative documents, course notes, or learning objects.

Institutional repositories typically do not do versioning and do not support complex or many author workflows, but they excel in preservation strategies (e.g., DSpace) and media independence and are championed by libraries. Learning object repositories on the other hand do not archive in the real sense but have special capabilities to handle formats for learning resources (e.g., IMS, SCORM) that some others do not typically integrate well and also provide support for multiauthor workflows and versioning distinct from archiving.

Leslie (2004) questions the difference between institutional repository software such as DSpace and FEDORA and “learning object repository” specialized software such as CAREO and notes that DSpace’s FAQ page promotes the software as being multipurpose and cross-functional.

Institutional repositories can also be differentiated from learning object repositories in term of their purpose. While the primary purpose of an institutional repository has generally been said to store, preserve, and showcase to the world the intellectual output of the university, the primary purpose of learning object repositories is to facilitate sharing and reuse of resources across disciplines within a university or college or across higher or further education sectors regionally, nationally, or internationally.

In the issue about whether general institutional repositories such as EPrints, DSpace, Fez, etc. could take on the functions of a bespoke learning object repository (e.g., Intralibrary), it is also relevant to distinguish between the two repositories. An institutional repository is made to be adapted. This is to say that university should be able to change the schema and the services to adapt to local requirements, but contrarily, a learning object repository is just too different and specialized. For instance, the EdSpace project at Southampton is running learning resources repository based on EPrints, but they are experimenting with the nature of a learning object repository by introducing open-access practices and sensibilities rather than keeping learning behind institutional firewalls. They are building something interesting (which shows signs of being effective as well), but they certainly would not claim to be trying to replicate a learning object repository.

The audience for the two repositories differs. Academic publications in an institutional repository are intended to be read by other academic staff and researchers, and they can access them directly from the repository. However, learning materials in a learning object repository are intended for students. The materials will generally be delivered to students through a different online system such as the VLE or a web page. In some cases the tutor has to download the resource from the repository and then re-upload to the student system or post the URL to the resource. Students would not normally have access to the repository itself, just the resource.

The two repositories can also be differentiated in terms of IPR, reuse, and citation. For institutional repositories, tutors have a relatively clear understanding of copyright and IPR rules for scholarly work, and there is an agreed framework for citation and reuse of publications. In the case of learning materials in a learning object repository, many tutors are uncertain about IPR; they are unsure if they are allowed to repurpose a particular resource as there is no agreed framework for this.

The types of material housed by these two repositories are also different. Collections

of learning object repository materials arise in different ways. According to Rothery and Hayes (2008), some are created by individual teachers as their personal work. Some may be resource collections such as a collection of digitized photographs for a particular course, a collection of sound recordings for departmental use, a collection of students' work, or past examination papers. The authors add that some resources may have been purchased by the institution commercially, while other materials may be the output of a curriculum development project. They conclude that there is considerable variety in the source of the material, its ownership, how it is used, and its format. On the other hand, scholarly publications in the institutional repository are of a more consistent type and format.

Another antecedent to differentiate between the two repositories is the issue of retention. There is a tradition of preservation and archiving of academic publications in institutional repository, whereas there is little awareness of any need to retain and archive teaching materials in a learning object repository.

The peer review issue is another difference worth mentioning when differentiating between an institutional repository and a learning object repository. Scholarly works in IR are often subject to peer review or quality assessment prior to publication. This is not the case with learning resources in the LOR. Rothery and Hayes (2008) point out that it is indeed a matter of controversy how one might assess the quality, as learning resources can be used in many different ways, and its value is very much dependent on how it is used. Authors would probably welcome feedback from other teachers, though this is a different form of feedback from that which is obtained from an editorial board on a research journal.

Similarities

Both institutional repositories and learning object repositories (Knowles and Bailey 2007) "relate to the management of information; are primarily concerned with internal information; require a

combination of technology, policies, procedures & user behaviour; rely on the participation and engagement of the user; involve resource discovery; impose centrally-determined controls around the behaviour of information; may require access to digital content in the medium-long term (T)he kind of things being stored in them are the same, there is volatility in those things, and the relationship between authors and those things is one on one or one to many."

Both systems ostensibly provide a searchable archive for digital materials from an institution. Not only are the materials typically different (e.g., scholarly research papers versus teaching-focused content and applications; PDF files versus zipped SCORM objects, Java applets, etc.), but "digital repositories," with their heritage in the library and archives world, typically support different metadata schemas and are focused on interoperating with different kinds of systems (library catalogues instead of, say, course management systems), and this embodies a different business logic (Leslie 2004).

Lynch and Lippincott (2005) reveal in their study that the kind of materials that are in repositories today and the kinds of materials that are planned for inclusion in the near future are not only e-prints and electronic theses and dissertations but digitized special collections material, multimedia, course material, and datasets.

Repositories hold different types of materials in their collections, and yet these materials are managed in the same way. Repository collections are there to give users access to digital versions of journal articles, conference papers, book chapters, unpublished papers, etc., directly via the repository interface (or portal/computer screen). As a rule, users do not need special accounts but can access the repository collection from home via Google.

Regardless of whether the scope of the repository is broad, and the institution uses a common software base for all types of digital collections, or an integrated approach linking separate platforms is taken, there appears to be a correlation between the implementation of learning object repository projects and an institutional repository.

Guiding Policy of Repositories and the Likely Content of the Policy

When establishing repositories, there are varieties of decisions to make. Policies, systems architecture, and other elements will depend on institutional context and the scope and purposes of the repository. Policies appropriate for an academic institution may not work in a corporate setting. Not-for-profit organizations have unique purposes and cultures that will dictate how their repositories are formed and maintained. In the light of this, the guiding policy and likely content of institutional repositories should include the following:

1. The institution should build and maintain a repository to provide a permanent record of the intellectual output of the university and maximize the visibility, usage, and impact of this through open access.
2. Repositories should operate as a non-profit, non-commercial, open-access, institution-wide repositories with the aims of preserving and disseminating the scholarly output and other selected outputs of the institution (university/college/research institution).
3. Repositories should contain approved collections and sub-collections that encompass the corporate, research, and learning and teaching activities of the university.
4. The university/college/research institution will normally expect staff members engaged in scholarly activity to deposit the resultant research and publishing outputs within the repository. These may take the form of preprints (subject to appropriate quality control measures), postprints, project reports, audit reports, published materials, etc.
5. Repositories should always contain the resources that the university regulations require to be deposited.
6. Libraries and learning resources should manage and develop repositories on behalf of the university.
7. All materials contained within the repository should comply with copyright legislation and, where appropriate, publishers' copyright policies.
8. All materials should normally be retained indefinitely.
9. Whenever possible, materials should always be made available on an open-access basis.
10. The metadata associated with the materials deposited in repository may be accessed free of charge, but it must not be reused in any medium for commercial purposes without formal permission.
11. Institutions should endeavor to ensure continued readability and accessibility of all items deposited in repository.

Challenges of Institutional and Learning Object Repositories

As pointed out earlier, repositories whether institutional repositories or learning object repositories are beneficial in many respects. However, there are a number of problems and challenges faced by institution implementing them. This section is dedicated to the discussion of this subject.

Van Earwage (2008) asserts that there are many challenges facing library and other staff who manage an institutional repository. One of the main challenges is faculty participation. Without the willingness of the faculty to contribute their works to the repositories, the collection cannot be sustained for growth. There are many reasons why the faculty may be reluctant to participate in a repository. Some of these reasons include fear of backlash from a publisher and a belief that depositing their work is too time-consuming or holds little value.

Additionally, some faculty members are weary of providing content to a system that contains gray literature that has not gone through the process of being peer-reviewed. There is the concern that the existence of student created content will in some way detract from efficacy their own professional research or writings. To combat a lackluster community requires much advocacy and education as well as the building of strong library-faculty relationships. The faculty must learn to trust the library staff in order to feel confident in contributing to the IR.

Another challenge is maintaining the balance between ease of deposit and the need for preservation. The costs and risks associated with digital preservation tend to grow when a digital collection includes a large number of diverse file formats, as was found in a study commissioned by JISC (James et al. 2003). It seems good practice to prescribe the file formats accepted by a repository and limit the number to a few that are based on open standards. However, this consideration should not become a barrier that prevents authors from depositing content into the repository. For the convenience of authors, most repositories will probably accept formats other than those that are preferred but will perform format migration for archival and preservation purposes.

It should be stressed that it is not possible or perhaps desirable to keep everything that has been created. Digital preservation involves selection and appraisal, which are criteria and processes for identifying information for long-term retention and preservation. Selection and appraisal are interactive decision-making points within the lifecycle of a digital object connected to its active use and can be applied to help ensure institutional resources which are devoted to the long-term availability of the most valuable digital assets. Guidance on good records management practices and how appraisal can be done within the context of institutional repositories, for different types of content, is needed to help decision-making and answer the questions “what to keep?” and “how long to keep?”

There are also a number of challenges that affect both the structure/architecture of a repository and its content. These include those listed under:

Structure and Standards

The design of a repository needs to address the distinction between “archival resources,” i.e., those that are likely to be of long-term value, and “non-permanent” or transitory, i.e., those that have a very short lifecycle. Another challenge is to design a repository structure that not only

accommodates both structured and unstructured objects but also provides a mechanism for potential sharing of both types.

Culture, Politics, and Practice

Sullivan (2004) emphasizes that those involved in institutional repository projects have reported that the effort and organizational costs required to address repository policy, content management, and promotion to academic staff dwarf the technical implementation effort.

Based on collective understanding of the problems associated with learning object repositories (LORs), Matkin (2002) identified several domains which contain significant barriers to the creation, maintenance, and implementation of effective LORs. These are summarized as standards, technology, pedagogy, culture, intellectual property, organizational development, business models, and policy. Matkin (2002) concludes that there are two other aspects underlying these domains of LORs that need to be considered. These are scale and convergence. Matkin explains that there are clearly scalability issues in the developing of LORs. Very large-scale LORs will need to operate very differently from small-scale LORs, particularly if the creation and maintenance of a community of users are important. In addition, there is a strong impulse to build repositories that can ultimately be combined, either actually or virtually. While the standards movement theoretically serves this impulse, differences in attributes not covered by the standards are significant potential barriers to combination.

Other challenges could include the impossibility of interchanging objects because of inconsistency in size and language, lack of consistent classification schemes, and variation in quality despite the attempts to institute peer review or quality criteria.

Projecting into the Future of IR

As put forward by Otando (2010), future plans in terms of raising awareness at the university, the

library plans to come up with strategies to sensitize all staff and to present the project to the university community before the launch. The strategies include:

- Organizing workshops and training and visiting colleges and departments to sensitize academic staff and researchers on the need for submission of their research into the IR.
- Using posters, presentations, brochures, university magazines, library newsletters, and UoN and library websites to publicize the service.
- Identifying “champions” in academic departments who can encourage their colleagues to take part is often the most valuable approach.
- Taking up the opportunities of school/college academic board meetings to publicize the service.
- Writing a press release announcing the launch.

By projecting into the future of institutional repositories in most of our higher educational institutions, an inside-in/outside-out model has been recommended by Lorcan Dempsey, Vice President of Membership and Research and the Chief Strategist at OCLC (see Fig. 4).

The “outside in” as explained by Lorcan Dempsey is the traditional role of libraries in acquiring external content for an internal audience, and “inside out” is the development of internal collections (archives, special collections, IRs) that are shared with an external audience. This framework is useful in understanding the growth of unique local and digital collections that have

different requirements in terms of staffing, systems, and the inherent and practical value to the institution. The books and journals that libraries acquire are a small portion of the digital content created by the academic community in the course of scholarship and learning. A much larger body of content in a growing variety of digital formats represents the output of the academic community and broader presentation of the dimensions of the scholarly information network. Scholarly communication is not limited to formal publishing. There are an expanding number of outputs in different formats that researchers need to access as part of the scholarly record. The IR writ large can house many of these formats, while others will be collectively addressed in disciplinary repositories.

However, a big question that comes to mind is the issue of sustainability. How will all the so-called IR created by our higher educational institutions be sustained? There is no doubt about the fact that library will continue to be relevant in terms of the management and maintenance of IR and more roles will continue to be created for libraries. Libraries therefore should endeavor to borrow leaves from the best practices around the world. For instance, Luther (2018: 14) explained that, “as the library’s role continues to evolve, some institutions, such as the University of Minnesota, have been able to analyze data that correlates student library activity with institutional metrics such as graduation rates, time to graduate, and returning students. Collaborating with other departments such as institutional research and IT to achieve joint objectives

Institutional Repositories Versus Learning Object Repositories, Challenges and the Way Forward for Higher Educational Institutions,

Fig. 4 Outside-in and inside-out model of scholarly communication in IR. (Source: Luther 2018)

also raises the profile of the library within the university and aligns it with specific goals of the institution.”

Luther (2018) emphasized further that anecdotes can be powerful tools for demonstrating the value of the IR since metrics often function as internal measures of platform performance for the library. Two examples of stories illustrate the role of the IR and its importance to other departments on campus. The Admissions Department at Illinois Wesleyan was enthusiastic about sharing student projects in the IR with prospective students and their parents to show the type of work being done at the university. Librarians at Utah State University gathered work from student-led interdisciplinary research groups in the sciences that highlighted the work of these communities, gaining greater attention for these programs beyond the university and leading to external funding for two projects.

To ensure that the IR is embedded in the university's information systems and services, the library in an institution should plan to develop an IR budget. The library should be in the process of soliciting for funds to buy facilities that can be used to establish the IR. Other future plans should involve enhancing staffing and skills, collaborating with other institutions to share technical skills, increasing collections in the repository, and providing access via the wide area network (WAN).

Conclusion and the Way Forward

This entry has examined institutional repositories and learning object repositories based on the argument that this area of research is being ignored by researcher over the years. Part of the key arguments to differentiate the two repositories centers on their definition, purpose, material and content housed, retention, audience, peer review process, etc. Argument about their similarities, on the other hand, relates to the fact that both institutional repositories and learning object repositories (Knowles and Bailey 2007) “relate to the management of information; are primarily concerned with internal information;

require a combination of technology, policies, procedures and user behaviour, etc.” It could be pointed out therefore that the key to a successful repository strategy will lie in the ability of repositories to share information and exchange records about learning objects and their provision of access to the objects themselves. In the light of this, the following are put forward as the way forward for higher education implementing these repositories:

Once prototypes have been developed for each of the starter projects, these will become pilot projects with academic staff involving faculty librarians, educational designers, and multimedia developers to test solutions and obtain feedback. The repository team should be keen to work with a school or center in managing their collection(s) of digital resources before rolling out the repository across all educational units.

Given the importance of resource discovery, it is anticipated that a new body should be organized to enhance access further. This body will continue to maintain close contact with institutional and learning object repository projects to share ideas and experiences. There is need for awareness of the benefits of ensuring there is interoperability across the higher education sector.

Universities and other tertiary educational institutions implementing repositories should continue striving to create a resource-rich, integrated learning environment that can be fully exploited by both students and faculty. A digital repository provides a flexible and discipline-independent mechanism for storing and managing digital objects, thereby enhancing integrating learning environments. In addition, university decision-makers should pay attention to maintenance issues.

Institutions implementing repositories should forget about their culture as this usually go a long way to serve as an obstacle on most occasions. Institutions should ensure careful selection of a core metadata scheme. This is to give room for consistency among the repository's initiatives. There should be consistency in the classification schemes, object, and size across institutional repositories. Issues relating to cataloguing of objects, retrieval of objects, organization and

archive, authorship, copyright, and language of the object will need to be resolved. There should be no variation in quality. Institutions should embark on or follow the same or similar peer review or quality criteria.

Moreover, there should be a common framework such as SCORM compliant for LOR in terms of technical issues. This typically consists of four components: (1) learning management system for managing the user and tracking progress through the content; (2) assets, specific web media such as HTML files, images, or video; (3) shareable content object for collection of assets that form a learning activity; and (4) content aggregation, an overall library of related content and shareable content objects. This idea is to promote integration of online learning products with learning management system (LMS) software.

Interactive Displays, Use of Interactive Charts and Dashboards in Education

Djordje M. Kadijevich
Institute for Educational Research, Belgrade,
Serbia

Synonyms

[Interactive graphs](#); [Interactive images](#); [Interactive reports](#)

Introduction

Interactive displays are digital artifacts that comprise one or more interactive reports (charts, tables, or summary measures). The main component of such displays are interactive charts.

Interactive Charts

Interactive charts are descriptive, exploratory graphical displays, whose content updates automatically whenever changes in data or variables

considered occur. These changes may be the result of data update (done by software or a person working with these charts or preparing data to be used by them), or actions done by the designer/user of these charts, regarding the selection of a particular variable value, examination of one variable instead of another, or the addition of a new variable to the set of variables being considered.

Interactive charts, which can be (relatively effortlessly) used to visualize regularities and trends in data (if any), are typically built in a drag-and-drop fashion within a digital tool or environment. As a rule, simple mathematical models lie behind the visualizations produced (e.g., frequencies, sums, and means), and these models are, after the designer's selection, automatically applied by the tool used.

Consider, for example, students' achievement in one school subject at a state examination. An educator may first consider this achievement by gender, by creating and using an interactive chart that displays the average achievements for boys and girls, signaling some pattern (with *achievement* as dependent, y-axis placed variable, and *gender* as independent, x-axis placed variable; Fig. 1 left). The educator may then examine whether this pattern holds true for a particular state region, by upgrading the design of this chart to summarize only data regarding that region (with *region* as filter variable; Fig. 1 center). Finally, the educator may examine whether the pattern is stable or changes from region to region, by finally enhancing this design to display the achievement in each region by gender (with *region* as an independent, x-axis placed variable, and the values of *gender* used as legend; Fig. 1 right).

Apart from traditionally used charts (e.g., pie charts, bar charts, line charts; see Figs. 1 and 2), other less common chart types may also be applied, such as area, bubble, and map charts. Such types may, for example, be found at <https://ncva.itn.liu.se/explorer/> and <http://app.rawgraphs.io/>. All interactive charts may be viewed as technology-supported images, no longer representing (complex) information as mere static figures but rather as dynamic, interactive objects.

Interactive Displays, Use of Interactive Charts and Dashboards in Education, Fig. 1 Chart (above) and its underlying design (below): from achievement by gender (left) via achievement by gender for one region (center) to achievement by region and gender (right)

Dashboards

Interactive charts are used as building blocks of dashboards, which are, in brief, sets of two or more interactive reports. These reports are mainly charts, but summary measures (and sometimes tables) may also be used (see Fig. 2). Dashboards are usually built in a drag-and-drop fashion like the interactive reports of which they comprise. Designing a dashboard, environment (dashboards builder) may thus only require its user to drag-and-drop some individual, previously created interactive reports onto a dashboard canvas (any of available built-in canvas or a user-designed one). There is often a possibility to add a filter to the dashboard to enable slicing of the data considered (e.g., to examine learning errors for all students together or individually for groups of students categorized by their gender or study program).

Initially created for the business world to display values of key performance indicators and signal when these values and their trends are good, acceptable or bad, dashboards have entered various industries, such as finance, transportation, healthcare, and sports (Wexler et al. 2017). They are becoming more and more common in the publishing industry (e.g., www.bookmetrix.com) and research evaluation (e.g., www.researchgate.net). A gallery of dashboards regarding various industries and areas can be found at <https://www.idashboards.com/dashboard-examples/>, for example.

What dashboards summarize in all these industries and areas are some performance indicators relating to various subjects and objects (e.g., assets, vehicles, patients, publications).

Educational Importance

It is no surprise that interactive displays, especially dashboards, have also entered education. They have been not only used to visualize learning outcomes (so-called learning analytics) but also to support work with data in various school subjects or university courses. Regarding such arranged work, if practiced within a suitable learning cycle (e.g., a mathematical modeling cycle), the work can support the understanding of this cycle and the realization of its values in capturing main features of disciplinary thinking, enabling also the development of important disciplinary notions (e.g., variable and functional dependence).

It is expected that many students will work with data as a foundation for their claims and actions regarding various professional issues. Such data usage, along with uncertainty, is central to STEM (science, technology, engineering, and mathematics) education (English 2016). As a result, there has been a noticeable demand recently for the inclusion of data science (i.e., the science of obtaining useful information from data by using various methods and tools) in

Interactive Displays, Use of Interactive Charts and Dashboards in Education, Fig. 2 Dashboard with two interactive charts and one summary measure: although not

dominant, overnight stays by foreigners are increasing (modified from Kadijevich 2016)

secondary education (e.g., Gould et al. 2017; <http://www.idssp.org/>), which may, at introductory levels, be realized using interactive displays.

Use of Interactive Displays in Education

Visualizing Learning Analytics

Dashboards are typically used to visualize learning data (Webb et al. 2018). With properly designed dashboards and suitable alerts complementing them (e.g., “Percent-correct score is below 40%!”), useful information about students’ learning (e.g., performance, engagement, interactions) can be provided to both students and teachers. A chart on a teacher dashboard may, for example, show that students who performed above average used various feedbacks (e.g., peer feedback, error correction feedback) more often than other students. Regarding a student dashboard, two charts may show that a student’s performance is below average and that his/her use of resources to aid learning is minimal. Various student and teacher dashboards are provided by the Graasp platform (<https://golab.graasp.eu>), for example.

Despite the promise of dashboards to improve learning and teaching, there is a limited knowledge of when, under what conditions, and to what extent the use of dashboards may improve them (e.g., Webb et al. 2018). Not only is there slim empirical evidence that learning analytic tools (e.g., dashboards) are effective for teaching and learning, but also learning analytic and its tools have also rarely been embedded in learning theories (Schumacher and Ifenthaler 2018). If, for example, to foster self-regulated learning, customizable student dashboards are advocated, we need a solid knowledge not only of student’s design choices (e.g., what he/she can see, what others can see, what source(s) of alerts can be) and their learning grounds and benefits but also of ways to resolve tension between personal autonomy and learning equity, taking care about anonymity and privacy (Roberts et al. 2017).

Promoting Different Kinds of Reasoning

Being able to support the viewing (and modeling) multivariate phenomena in a less complex and

more dynamic way than the traditional, paper-and-pencil one, interactive displays can be suitable means to foster statistical reasoning, particularly statistical literacy (SL). Apart from traditional SL components (e.g., representing and interpreting data; finding patterns and trends in data), the use of these displays can foster the development of some novel SL components, such as the notions of effect size and interaction associated with the analysis of multivariate data (e.g., Ridgway et al. 2013; Kadijevich 2016). (A visualization that, on average, males score 5% higher than females shows an effect size, whereas a visualization that there are different achievement patterns for males and females due to technology use signals an interaction between gender and technology use.) Research evidenced that these notions could be grasped by many statistically naïve secondary students when they used interactive displays available at <https://www.dur.ac.uk/smart.centre/freeware/> (Ridgway et al. 2013). To cultivate various SL components, as part of statistical reasoning, the use of dashboards may be practiced within an appropriate learning (e.g., data science) cycle, whose steps (stages) may be ask questions, consider data, analyze data, and interpret data (Gould et al. 2017).

Although the term data modeling has primarily been used in statistics (to denote searching for a stochastic model of data considered) and computer science (to denote a process that describes the content of a database), it has also been used to denote the work with data aiming at representing and interpreting data. To empower such data modeling (based on designing and applying multiple representations), interactive displays may be used. Sharing many common underlying skills with mathematical modeling, this kind of data modeling can be viewed as an instance of mathematical modeling. If aimed at prescriptive modeling (i.e., to recommend well-grounded changes of the world modeled), data modeling (or modeling with data) may follow a learning cycle that comprises six key activities (stages) – asking questions, preparing data, visualizing data, answering questions, validating modeling, and recommending changes (Kadijevich 2018). The application of this cycle would not only promote main features of mathematical reasoning (with respect to

developing, solving, applying, and improving simple models) but also enable the development of important mathematical notions, such as variable (dependent vs. independent) and functional dependence (linear vs. nonlinear).

The stage of preparing data (that will be visualized using interactive displays), which is present in both above-mentioned learning cycles, calls for various (mostly computational) thinking skills, such as organizing, structuring, collecting, querying, transforming, and auditing data. This means that apart from statistical or mathematical thinking, computational thinking (CT) may also be cultivated. CT basically denotes thinking processes involved in problem-solving with computer by applying tools and techniques from computer sciences. Provided that a versatile computer environment is used, data practice using interactive displays would also promote CT strategies, such as decomposition as well as rapid prototyping, top-down, and bottom-up approaches (Kadijevich 2019). The design of the dashboard presented in Fig. 2 may be the result of decomposition, whereas the dashboards presented in Fig. 1 may be built in a rapid prototyping fashion (i.e., an iterative process through which we incrementally show what one display will look like). A top-down approach is applied when we go from a dashboard as a whole to its individual reports as parts, whereas a bottom-up approach is used when we start from some individual reports and combine them to create a dashboard (these approaches are often combined).

Conclusion

To empower data practice aiming at representing and interpreting data, we may use specific digital tools called interactive displays. Through their use, we can visualize various learning measures, hopefully improving learning process and its outcomes. However, it is not clear when, under what conditions, and to what extent the use of such displays can improve learning, which may be explored in future studies.

Through the use of interactive displays we can also promote important disciplinary notions (e.g., linear vs. nonlinear functional dependence). And, if their application is practiced within a suitable learning cycle (e.g., data science cycle), such application can support the understanding of this cycle and the realization of its values in capturing main features of disciplinary thinking (e.g., statistical reasoning). However, although mostly based upon simple mathematical and statistical models, the use of interactive displays can generate a number of challenges (e.g., what measures to use; what charts to apply; what variables to use as legend and filter). Furthermore, various challenges may also be generated by the software used for developing these displays (e.g., how to build displays of increased structural complexity). These challenges may be better understood and pedagogically addressed if examined within a learning cycle with respect to its steps (stages) and transitions between them (Kadijevich 2018). Because our knowledge about the challenges and pedagogical ways of addressing them is scarce, further research may examine these issues in detail.

To foster self-regulated teaching or learning based on learning analytics, customizable interactive displays may be used, which would call for research studies focusing on design issues of such displays and their educational values. When the displays are used to promote disciplinary reasoning, these design issues may include some intelligent support, regarding, for example, assessing data quality, connecting simple and complex displays, and signaling possible data regularities in displays produced.

Intercultural Education in the Digital Age

Miri Shonfeld
Kibbutzim College of Education and MOFET,
Tel Aviv, Israel

Synonyms

[Empathy education](#); [Multicultural education](#)

Introduction

Intercultural education and multicultural education are interchangeable terms that intend to educate people to appreciate living and knowing

diverse cultures, by learning with students from different backgrounds, nationalities, and cultures. Some writers suggest that there are differences between the two terms, but a recent study argued that they have many areas of overlap and that the different use of the terms is mainly caused by the fact that multiculturalism is the term widely used in the United States, whereas interculturalism is more frequently used in Europe (Holm and Zilliacus 2009). The entry considers the subject matter of intercultural education per se and the contribution of information and communication technology (ICT). It describes various policies and visions that promote learning about others and models of working collaboratively together. The focus will be on the digital area and how ICT contributes to the possibilities open to educators, policy makers, and practitioners to create innovative intercultural education. It will show a few examples that stress the value of ICT to increase opportunities for intercultural education.

In the digital era where globalization and migration are part of education, it is difficult to define cultures and determine how much it is related to nationality, religion, or identity. Culture includes traditions, heritage, language, religion, ancestry, aesthetics, thinking patterns, and social structures. As noted by the UNESCO (United Nations Educational, Scientific and Cultural Organization):

The current era of globalization, with its unprecedented acceleration and intensification in the global flows of capital, labor, and information, is having a homogenizing influence on local culture. While this phenomenon promotes the integration of societies and has provided millions of people with new opportunities, it may also bring with it a loss of uniqueness of local culture, which in turn can lead to loss of identity, exclusion and even conflict. This is especially true for traditional societies and communities, which are exposed to rapid 'modernization' based on models imported from outside and not adapted to their context. (UNESCO 2017)

The digital world could in one way destroy cultures but in another way can revitalize them (Resta et al. 2018). The Internet is creating a new culture and helping globalization to spread, but it also provides new opportunities where people can learn how to express their culture. The Internet

seems to decrease distance between cultures in one respect and increase cultural destruction on the other. In terms of languages, it might promote the dominance of one language, but on the other hand it raises the importance of language awareness (Finkbeiner and Knierin 2015). Therefore, knowledge and the acceptance for diverse cultures are much more important now than in the past.

Intercultural Education

There are four goals in education for an intercultural approach. The first is accepting the narrative of the other side and what this narrative implies as legitimate, without necessarily agreeing with the narrative. A second goal is to critically examine the contribution of the "my" side when there is conflict and what this entails, including the suffering of the other side. The third goal is to feel empathy for the other's suffering and to build mutual trust. The fourth goal involves an attempt to resolve conflicts in non-violent ways (Salomon 2000).

There are several stages in the ladder of goals for intercultural education. The first stage is a fatalistic acceptance of the presence of the other, as a solid given, unchangeable as a "necessary evil," sometimes out of hope or belief in the temporariness of the situation. The second stage is calculated, logical tolerance, which overpowers recoil or disgust of the other, usually out of a basic commitment to the values of humanism and political correctness. The third stage is the "anthropological" recognition of the other, out of curiosity and empathy, usually accompanied by a certain sense of superiority. The fourth stage is a sincere and genuine dialogue with the other, based on equality and mutual respect. The fifth stage is willingness for intercultural interaction between oneself and the other; and the sixth stage is a cultural merger, partial or complete (Tadmor 2003).

Wurzle (1988) presents a seven-stage model of education with an intercultural approach: the first stage, the beginning of monoculturalism; the second stage, the beginning of intercultural communication; the third stage, intercultural conflict, a

crisis that may arise as a result of intercultural contact; the fourth stage, educational intervention designed to heal the rift created during the conflict phase; the fifth stage, following the learning, the upsetting of the balance and confidence of the absoluteness of one's culture; the sixth stage, the formation of a new awareness toward oneself and toward the other; and the seventh stage, the integration of an intercultural perception.

In order to implement intercultural education, a structural change is needed which includes a change in the curriculum, learning materials, teaching and learning styles, perception and behavior of teachers and principals, and goals, norms, and culture of the school. In order to be able to bring about a significant change in the education system, intercultural education must be comprehensively implemented; this involves (1) integration of content, (2) building knowledge, (3) reducing prejudice, (4) egalitarian pedagogy, and (5) empowering the school's culture. In many countries those conditions are absent.

In a study conducted by Shapira (2008) in four schools with immigrant children, there was no trace of actual training to work in an intercultural system and about one-third of the staff members had attitudes that made it difficult to cope with the absorption of migrant children. Attitudes toward parents ranged from prejudicial to negative remarks toward the immigrants and attempts to bring them closer – often from a paternalistic perspective – and attempts to “educate” them. It seems that these attitudes are similar to those which were common in Israel in previous years.

Policies on Intercultural Education

Countries adopt a variety of approaches toward ethnic diversity in their societies: (1) assimilation, (2) liberalism, (3) regulation/division of power, and (4) intercultural policy. The first model – assimilation or the melting pot – tends to eliminate diversity in favor of a common denominator between the various groups that make up the society. The use of such a policy in the United States, for example, was aimed at immigrants who came from different parts of the world. Another

example is the melting pot in Israel in the 1950s, in which they tried to change the culture of immigrants, believing that only such a change would enable them to fully integrate into society. In this model, the state and its various organizations play a central role in the change processes which are designed to integrate newcomers or different ethnic/religious groups into society.

The liberal approach adopts cultural neutrality. The demands of the liberal state from its citizens amount to the acceptance of the basic democratic rules of the game, and the national identity, in this case, becomes essentially procedural (Habermas 1992, 2001). The ethnic-cultural identity, like religion in a secular state, reflects a preference, however important, that the state's citizens can express in their personal lives, but it is not really the state's business (Kymlicka 1995). It is the state's role to ensure equality among all its citizens and to prevent any form of discrimination derived from their cultural diversity.

Countries such as Canada and Australia have transformed their national definition into a multi-cultural identity designed to contain the different groups within them. The Australian government has adopted a national agenda for multiculturalism built on a three-tiered approach: the right to preserve cultural identities, the right to social justice and equality of opportunity, and the need to realize the economic potential and capabilities of all Australian citizens. Nonetheless, cultural diversity was limited by the insistence that the various groups comprising Australian society should be committed to the nation, to accept the basic principles of Australian society and to the recognition of the right of others to express their culture and worldly views. This fundamental statement was translated into symbolic representation of the various groups and their access to services and resources. In Canada too, where multiculturalism became an official policy in 1971, four main goals were formulated: supporting ethno-cultural groups' culture, helping these groups overcome obstacles of integration into society, encouraging meetings between various groups, and assisting immigrants in learning the official language of the state (Kymlicka 1995). At the heart of Canada's multicultural policy is the

assertion that all citizens have the right to preserve their culture and share it with others because their culture and language deserve to be preserved and strengthened with the assistance of state institutions and that all government institutions should adopt a policy that enables all the various groups to integrate into society and to encourage understanding and respect for diversity in Canadian society.

In African countries diversity is part of life since they are divided into different tribes. In Ethiopia, for example, the government officially adopted multicultural policies in 1991. Those were aimed at recognizing and allowing members of distinct groups within that society to celebrate and maintain their different cultural identities as a way to promote social cohesion. However, research done in schools calls for better implementation of multiculturalism (Solomon 2011).

In Britain, a committee was established, the Parekh Commission, whose main goal was to transform “multicultural emotions” into an informed process of structural changes in the patterns of action of the state and its various institutions. The committee summarized its vision as follows:

We believe it is possible and essential to create a society in which all citizens and communities feel valued, have equal opportunity to develop their skills and live a life full of content, receive a fair share of the collective responsibility and help create a community life characterized by a spirit of brotherhood, common identity and a sense of purpose that is compatible with the love of multiplicity and diversity. (Parekh 2000)

In Germany, diversity is a contested issue due to the government policy of accepting Turkish workers and in recent years, refugees from Africa and Muslim countries. The German government sees intercultural education as an important role for teachers to implement in schools. In addition to policies, they assert that diversity has a potential for getting to know others and their own culture. They support language awareness and stress that studying languages promotes intercultural competence (Kultusministerkonferenz 2013).

Shared education is the policy adopted in Northern Ireland to enable schools that are mainly

Protestant or Catholic in ethos to work more collaboratively together. After an initial phase of work, built around the notion that contact should be entirely face-to-face, Austin and Turner (2018) reported on work that started in 2017 when teachers were given professional development on how to use blended contact. No firm conclusions were reached about whether there was an agreed order in which to deploy the three elements of interaction, namely, asynchronous contact through a virtual learning environment, synchronous contact via software that offered real-time interaction audiovisually, or actual face-to-face contact.

Various countries have adopted a policy that can be described as multicultural, which has at the core recognition of group rights and adapting policies to the needs of ethnically diverse groups. But multiculturalism as a public policy provokes objections for the reasons mentioned earlier. Thus, for example, the declarations by British Prime Minister David Cameron and German Chancellor Angela Merkel that “multiculturalism has failed” bring back to the center of the debate not only the usefulness of the multicultural policy but also the alternatives to the democratic management of a heterogeneous state (Dobbernack 2010) and the rethinking of softened models of assimilation (Brubaker 2001).

ICT and Intercultural Education

In recent years, the use of online projects that offer collaborative learning in a multicultural environment and even between hostile cultures has been increasing. Information and communication technologies serve as a significant lever for learning, with affordances for various teaching and learning approaches. The digital environment enables the formation of heterogeneous groups that were not possible in the past due to physical limitations. Such an environment creates learning opportunities with students from different cultures and countries (Austin and Hunter 2013; Shonfeld 2017). It allows for the formation of relationships without the influence of stereotypes that may arise from external appearances (Shonfeld et al. 2013).

It can even contribute more successfully than a face-to-face intercultural meeting (Hasler and Amichai-Hamburger 2013).

In general, studies show that extended online contact between groups, in other words, without direct contact, may promote positive approaches among individuals who do not belong to the same group. Such contact may also promote tolerance toward foreigners, immigrants, and people without status and groups suffering from stigmas and reduce hostility between long-standing rival groups such as Catholics and Protestants in Ireland. Studies also show that intercultural interaction leads to greater willingness to seek real future contact among group members, including between majority and minority groups (Cameron et al. 2007). In specific cases, a change in prejudice as a result of digital contact was made in relation to Muslims and Christians in Australia (White and Abu-Rayya 2012) and Arabs and Jews in Israel (Walther et al. 2015).

Turner and Cameron (2016) underlined the potential value of blended contact in providing a means for young people to have much more frequent contact than would be possible through face-to-face work. Harwood et al. (2016) refer to the ways that online contact can overcome three of the challenges of face-to-face contact, namely, practicality, anxiety, and sustainability. These findings were confirmed by Austin et al. (2017) who demonstrated that ICT can supplement face-to-face work, notably by providing longer-term engagement between pupils than would otherwise be possible and offering teachers a model which is better able to fit into the demands of a busy teaching day.

Examples of Projects that Use ICT to Connect Cultures

TEC (Technology, Education, and Cultural Diversity)

The TEC model that was funded in Israel harnesses ICT to support intercultural education. It implements a gradual collaborative learning model based on advanced technologies for teachers, pre-service teachers, and pupils from

different ethnic groups and religions, yielding constructive dialogue and cooperation between diversified groups and eventually tolerance and mutual respect (Shonfeld et al. 2013).

The collaborative learning model of advanced Internet technologies is implemented within small teams from diverse cultures by the educators of the participating groups, progressing gradually from online communication (written, oral, video) to face-to-face interaction (Hoter et al. 2009). Through collaboration in joint assignments over a period of 1 year, team members get to know each other, develop mutual respect, eliminate stigmas, and reduce mutual prejudices. The in-service educators then implement the program in public schools and thus serve as major agents of social change, having influence on generations of students. Research has shown that the TEC model yields what have stated as “outstanding results” (Walther et al. 2015).

The TEC Center’s goal is to embed the model of online cooperative learning in the school system to change preconceptions, prejudices, negative opinions, and stereotypes that affect Arabs and Jews, and religious and secular Jews in Israel, from an early age. The program’s goal is to develop intercultural relations in cyberspace, connect young children in the school system, and start a discussion leading to understanding between the different cultures in Israel’s divided society.

The ABCs

The ABCs stand for autobiography, biography, and cross-cultural analysis which involves cultural self-analysis of differences and communication. It is a classroom model that develops cultural understanding and intercultural competence (Schmidt 2006). Its rationale is based on the idea that students, who write their biography, interview and write an autobiography of a colleague from a different culture and then carry out a cross-cultural analysis that will improve their communication skills as well as their intercultural competencies. This model moved to a digital platform, the intercultural exchange project, called ICE (the online intercultural exchange program).

CoGI

CoGI is a collaborative online program between students in Germany and Israel. It integrates the ABC's model with the TEC model. Students work online to create a product. However, they get to know each other and do the analysis when looking at similarities and differences between the different cultures (Finkbeiner et al. 2019). This project started in 2013 as a collaborative program between 2 instructors with 40 students and continued with more than 100 students and 5 instructors from different institutes.

Soliya

Soliya is a connect program that uses a digital platform. Its purpose is to empower young people to create connections within and between continents such as Asia, Europe, and North America. The starting point guiding the project is that of global citizenship – one that establishes awareness of the interdependence of individuals and systems – and the duty of responsibility derived from it. From this starting point, there is a need for continuous movement from individuals and communities toward a number of stages: improved intercultural communication, inclusive meetings within cultures, greater cultural awareness, and the realization of shared destiny and the need to find common solutions that will benefit all (Roberts et al. 2013).

The project is based on the development of dialogue which has five goals: (1) developing cross-border communication skills, which means the ability to be constructively involved in different environments in order to achieve a stable solution to common problems; (2) the development of empathy, which is the ability to build relationships and connect with other participants with respect and appreciation; (3) developing critical thinking; (4) promoting awareness, which means the ability to strive to understand and comprehend the basis of feelings, assumptions, values, and biases that shape different positions; and (5) activity. This includes the development of long-term interest in intercultural communication and involvement in opinions, in different cultures and values (Fournier-Sylvester 2016).

The Dissolving Boundaries Program

Following the Belfast Peace Agreement of 1998, the locally elected administration in Northern Ireland and its counterpart in Ireland set up the Dissolving Boundaries program which was funded from 1999 to 2016 and involved some 50,000 young people. Evidence has emerged from evaluation of this project that a blended approach has been welcomed by teachers. In the design of this work, the combination of the contact hypothesis (Allport 1954) and the reach of the Internet was found to be critical (Austin and Hunter 2013; Hasler and Amichai-Hamburger 2013). Moreover, recent research indicated that even a year after the contact came to an end, pupils displayed more interest and knowledge than matched pupils who had not been involved (Rickard et al. 2014). Their findings were confirmed by external inspection of the program (Education and Training Inspectorate, 2010/2011) and external evaluation (Bonnell et al. 2010). Key conclusions showed that pupils gained better understanding of each other and developed enhanced ICT skills. Teachers also gained extensive professional development through having to use ICT to plan joint work with teachers in another jurisdiction.

The E-Partners Program

Lessons learned from Dissolving Boundaries program use of blended contact, with schools that were some distance apart, were used in the development of the E-Partners program which ran from 2013 to 2015 and linked schools within Northern Ireland with the support of student mentors. Austin et al. (2015) reported that blended contact between two academic grammar schools had enabled teachers to appreciate the value of blended contact when faced with the demands of a crowded curriculum and examination pressures. A follow-up study the next year with 28 primary schools working in 14 cross-community partnerships found strong support for blended contact (Austin 2019).

Honey Bee Network: India

The Honey Bee Network comprises a comprehensive multimedia and multilingual database of

primary educational resources in native languages as well as information relating to innovations and ideas, including horticulture, biodiversity, and herbal medicine. In the same way that honeybees thrive on pollen from flowers, the Honey Bee Network is designed around the principle of information and knowledge sharing for the common good. By facilitating the cross-cultural and multi-linguistic exchange of ideas, the Honey Bee Network provides an opportunity to tap into the creative component of indigenous knowledge systems. The Honey Bee Network affords geographically disadvantaged peoples an opportunity to share their creations and ideas with their peers in other parts of the country and the global community (Honey Bee Network 2017).

TARASA

TARASA is a new initiative in Israel which enables everyone and everywhere to preserve and share any memory (text, photo, and video) without any preferences or cataloging. The very attractive and accessible website is based on the idea of relating all the memories to the relevant places and times on a global digital map (TARASA 2017).

The basic concepts of TARASA are that any memory which is meaningful to someone should be documented and preserved, that memories create a community, and that a social digital framework which brings together the memories of various communities can lead to curiosity, equitable reference, and mutual respect. TARASA creates a free space which is especially open to the memories and voices of excluded social sectors which have not been properly represented through dominant collective memories.

Discussion and Summary

The previous sections of this entry show that intercultural education is a moral imperative in a world which is experiencing both migration and population displacement on an unprecedented scale. Most young people are growing up in schools that are ethnically diverse and at a time when the reach of the Internet is making

both local and global communication via the Internet inexpensive and accessible (UNESCO 2011).

To address the challenges of developing social cohesion, online interaction and blended contact have been shown to make lasting differences to students' perceptions of each other (Rickard et al. 2014). In addition to political will at government level, teachers need professional learning to embed this kind of work in their daily working lives. That learning needs to be built around the principle that ICT communication software is not so specialized that only teachers who are technology experts can make use of it. It needs to be designed so that it is within the reach of any classroom teacher so that intercultural education can be developed through a wide range of different curricular topics.

In the broader context of the whole school, leaders need to develop a vision for their institutions that is both outward-looking and inclusive. Every child, irrespective of their ability or special needs, should be able to participate in classes which have an intercultural focus. Moreover, given that some of this work may challenge preconceived views of "the other," school leaders need to think carefully about how they include parents in intercultural education. Where schools have a strong connection to their local communities, parents can be drawn in naturally to intercultural programs, not least when their children use the Internet at home to extend the work they are doing in schools.

However, there would be little chance of this work becoming embedded in the curriculum without teachers and pupils having adequate access to an ICT infrastructure that provided high-quality Wi-Fi connectivity, hardware, and appropriate software. Different countries adopt a variety of approaches to this challenge.

There remain formidable challenges to this kind of work; examples abound where important projects simply grind to a halt when external funding and support is removed (Austin 2019). Farsighted politicians and administrators need to find ways to embed intercultural education in the curriculum and to be clear about what its outcomes should be.

In far too many parts of the world, the basic infrastructure is not yet in place on a regular basis to facilitate blended contact as a normal part of the curriculum. Even when it is, numerous papers note that ICT is being underused. For example, in Australia, Prestridge (2012) cites evidence that “only a minority [of learners] are reaping the benefits of the information technology revolution” and there are similar concerns expressed for Turkey (Goktas et al. 2008), Norway (Krumsvik 2014), the United States (Foulger et al. 2017), and Spain (Gil-Flores et al. 2017).

However, when we count the cost of not enabling young people to learn about each other, we can see the dangers that can arise from children learning in monocultural settings. Prejudice flourishes when the right kinds of contact with others are absent or limited. Stereotyping of others by class, ethnicity, or religion is often the start of a process which can lead to discrimination and conflict.

Evidence in this entry showed that the use of ICT, particularly as part of blended contact, can make a lasting impact on young people and their teachers (Austin and Hunter 2013; Walther et al. 2015). But it will require sustained political will both internationally and nationally to reap the considerable benefits of this work and ensure that it becomes the norm rather than the exception in schools.

Synonyms

Computer science olympiad; Computing olympiad; Contest in informatics; IOI; Programming contest

Introduction

Recently in many countries educators and families have raised a question about what is the real effect of new smart technologies in the learning outcomes of the school education. Obviously, the smartphones and services provided by them are considered to pose a threat to the traditional teaching and learning. There are a lot of discussions in media about this topic. Following the trends, the educational authorities are producing new types of policy papers to tackle the issue. The computer play industry is flourishing, and consequently computer programming is becoming a more and more popular subject in the schools.

Although informatics is not taught as a discipline in many countries, school students are invited to participate in an informal training and different contests on informatics organized all over the world. Contests are exceptionally valuable for motivating and involving students in computer science (informatics). The current entry discusses the Olympiads in informatics arranged internationally and continuously. The main attention is paid to the model of International

Olympiad in Informatics, or IOI – abbreviation that computer science education community has used. But there is some discussion about the local and national contests. The relatively long history of the IOI proves that computer programming has a very strong attraction to school students making the IOI competition an intellectual fulfillment of the year.

The commonly used informal way to introduce informatics in education is to attend contests and Olympiads on programming. Contests make learning programming more attractive for students, help them to develop problem-solving and computational thinking skills. Social aspects increase motivation to communicate with other students, and during contests students meet their peers from all around the country or countries, make friends, and wait for the next competition ready to show that their abilities have improved since the last participation.

Petar S. Kenderov in his article “Three decades of international informatics competitions (How did IOI start?)” has studied the roots of the International Olympiad in Informatics (Kenderov 2017). The IOI was initiated in Bulgaria with support of the United Nations Educational, Scientific and Cultural Organization (UNESCO). In October 1987, the Bulgarian delegate Professor Blagovest Sendov proposed in the 24th General Conference of UNESCO in Paris the idea of initiating international Olympiads in informatics for school students.

After 2 years, UNESCO initiated and sponsored the first IOI which was conducted in Pravetz, Bulgaria, from 16th to 19th of May 1989. The Olympiad was modeled after the International Mathematical Olympiad (IMO 2018). For instance, the participating countries were required to send sample problems to local organizers in advance from which the International Jury had to select the problems to be given at the competition.

In the first IOI, 13 countries participated: Bulgaria, Cuba, Czechoslovakia, Federal Republic of Germany, German Democratic Republic, Greece, Hungary, People’s Republic of China, Poland, the Soviet Union, Vietnam, Yugoslavia, and Zimbabwe. Teams consisted of four students and two

team and deputy leaders; only the teams from Hungary and from Yugoslavia had two students each. Bulgaria participated with two teams and the Soviet Union with three teams. Thus, altogether, there were 46 students in 16 teams participating.

Only participants younger than 19 years old by the beginning of the competition were admitted. In the first half hour after the start of the competition, the participants had the right to put questions to the International Jury (in written form) concerning the formulation of the problems. The student work was preliminary checked and assessed by the respective team leader and then finally marked by the official coordinating commission. The final marking was with the International Jury which needed also to decide how many first, second, and third prizes are to be given to most successful participants.

The IOI is one of international science Olympiads designed for the four (with exception of IOI in 1995 when the Netherlands allowed five students in a team if at least one girl was chosen) best high (upper secondary) school students from each participating country selected through internal National Science Olympiads.

The IOI is organized annually in and by one of the participating countries. Each participating country typically sends a delegation of four contestants and two accompanying adults. Location and dates of the previous IOI are as follows:

Tsukuba, Japan, September 1–8, 2018
Tehran, Iran, July 28–August 4, 2017
Kazan, Russian Federation, August 12–19, 2016
Almaty, Kazakhstan, July 26–August 2, 2015
Taipei, Taiwan, July 13–20, 2014
Brisbane, Australia, July 6–13, 2013
Sirmione-Montichiari, Italy, September 23–30, 2012
Pattaya, Thailand, July 22–29, 2011
Waterloo, Ontario, Canada, August 14–21, 2010
Plovdiv, Bulgaria, August 8–15, 2009
Cairo, Egypt, August 16–23, 2008
Zagreb, Croatia, August 15–22, 2007
Mérida, Yucatán, Mexico, August 13–20, 2006
Nowy Sącz, Poland, August 18–25, 2005
Athens, Greece, September 11–18, 2004
Kenosha, Wisconsin, USA, August 16–23, 2003

Yongin, South Korea, August 18–25, 2002

Tampere, Finland, July 14–21, 2001

Beijing, China, September 23–30, 2000

Antalya-Belek, Turkey, October 9–16, 1999

Setúbal, Portugal, September 5–12, 1998

Cape Town, Republic of South Africa, November 30–December 7, 1997

Veszprém, Hungary, July 25–August 2, 1996

Eindhoven, the Netherlands, June 26–July 3, 1995

Haninge, Sweden, July 3–10, 1994

Mendoza, Argentina, October 16–25, 1993

Bonn, Germany, July 11–21, 1992

Athens, Greece, May 19–25, 1991

Minsk, Belarus, July 15–21, 1990

Pravetz, Bulgaria, May 16–19, 1989

The IOI host countries are usually selected from among the candidate countries 3 years ahead of the IOI in question. The selection is made in the International Committee of the IOI. In 2019 the IOI will be held in Baku, Azerbaijan, 2020 in Singapore, 2021 in Egypt, and 2022 in Indonesia. Each IOI organizing country has published a website of its own containing all official information, news, etc. In addition the IOI is maintaining an official website for general information about the IOI (2018).

Contests on Algorithms and Programming for School Education

To find jobs in the future, students also need to be able to have a deep insight in many issues like solving problems creatively, work in teams, communicate clearly in many media, learn ever-changing technologies, and categorize a flood of information. Developing abilities to master modern technologies and skills for solving problems is among the most important capabilities of an educated future citizen of the twenty-first century. Technology literacy and information literacy are one of the most important citizen's literacy skills. Today the emphasis is on deep thinking skills or understanding going beyond technology. Computational thinking is one of the most important future abilities which include abstraction,

analyses, data handling, pattern recognition, modeling, simulation, as well as problem-solving using algorithms and programming languages.

Programming, with emphasis on algorithms, remains the core of contests and competition and stimulates the learning process. Programming is an activity composed of several components: comprehension of the problem, choosing algorithm, encoding it, debugging, testing, and optimizing. Since many of the skills required for successful programming are similar to those required for effective problem-solving, computer programming and particularly choosing one of several possible solutions and later debugging in a short period of time provide a fertile field for developing and practicing problem-solving skills in an environment that is engaging for young students.

There have been many academic competitions and contests in computer science all over the world. Most of them are programming contests with focus on algorithmic problem-solving.

Two main paradigms for implementing contests are common over the world: from an international level to the local one (top-down strategy) and vice versa and from local activities to an international promotion (bottom-up strategy). The first paradigm is a challenge to find some suitable international contests, analyze, train students, and join them after intensive work. The second paradigm stresses an opportunity to establish the local contest and attempt to develop it to an international level. The IOI is a contest referred to the first competition paradigm, while the *Bebras* international challenge on informatics and computational thinking (Bebras 2018) belongs to the second paradigm. The main issue of contests is task; they should be interesting and systematically prepared, recognizable by computer science community, etc. (Dagiene et al. 2017). Finding interesting and adequate tasks that can be solved in a few minutes seems to be much more difficult in the field of informatics than in the field of mathematics.

Olympiad movements in many countries and regions can be considered as the most significant contribution of the IOI to computer science education. Only 13 countries participated in the first

IOI, whereas nowadays more than 80 countries are involved. Almost all these countries organize national local contests or Olympiads in informatics to train students as well as teachers. Some of these contests were implemented following the IOI model (with some adaptation to national peculiarities), although some countries are concentrated on their own infrastructure of contests. Additionally, there are regional Olympiads in informatics, e.g., African, Asian, Arabic, Balkan, Baltic, and Central European. Usually they are organized in the same manner as the IOI.

Structure of the International Olympiads in Informatics

According IOI Regulations (IOI 2016), the primary goal of the IOI is to stimulate interest in informatics (computing science or computing) and to bring the discipline of informatics to the attention of young people. Another important goal is to discover, encourage, bring together, challenge, and give recognition to young people who are exceptionally talented in the field of informatics and to have them share scientific and cultural experiences. Also, it is significant to foster friendly international relationships among computer scientists and informatics educators. One of the main objectives in each country is to discover, encourage, and train exceptionally talented young people in computer science.

Competition takes place during 2 competition days both of which are directly preceded and followed by a noncompetition day. The contestants are required to solve the competition tasks given to them, together with any translations and materials permitted by the competition procedures. Evaluation is to be carried out directly after the competition in accordance with the judging procedures.

A national delegation of a country is to be headed by a team leader and a deputy team leader. The maximum number of students is four. The delegation could also be observing: then it may include only a deputy leader but no contestants. The team leaders have the obligation to translate the tasks to a language which the students

understand. The leaders also have the responsibility to make sure that all members of the national delegation abide completely to the competition rules.

Guides have an important role in the IOI event. Traditionally every delegation has its own guide during the IOI week. The contestants usually need more guidance than leaders, guests, and other participants. The guides' duty is to introduce the environment to the delegation, for example, the venue, the hotel, the cafeteria, the city, etc. They make sure that everybody is in the right place at the right time. They attend the excursions and spend leisure time with the contestants.

A contestant is a student who was enrolled at a school for secondary education during the period September to December in the year before IOI. Contestants are not older than 20 years on the 1st of July of the year of IOI.

The students compete individually and try to maximize their score by solving a set of problems. The IOI contestants are required to express their algorithms in one of the allowed programming languages, currently Pascal, C/C++, and Java (Pascal will be removed from the list probably by 2019.). The contestants must engineer their programs to run flawlessly, because grading is based on automated execution.

Bodies and Committees

The IOI is managed by the General Assembly (GA), which is a temporary, short-term committee composed of the leaders of all the participating countries and by several long-standing committees. The International (Steering) Committee (IC) consists of representatives of the past, present, and future IOIs as well as several elected representatives. Its task is to retain the continuity of the IOI by finding future host countries. The second committee is the IOI Scientific Committee, the task of which is to ensure continuity and quality control of the IOI competitions.

The IC is a long-term standing committee. It consists of 11 voting members, all from different participating countries, plus a nonvoting secretary. The main task of the IC is to supervise the continuity of the IOI by finding future host countries, examining the organization of future IOIs,

solving problems encountered during the organization of an IOI, evaluating past IOIs, and adjusting the format and content of the IOI to ensure that the IOI goals will be met in the future.

The IOI international Scientific Committee (ISC) was established at the GA Meeting in 1999, at IOI'99 in Antalya-Belek, Turkey. The ISC consists of past, current, and future IOI host countries and members elected by the General Assembly. Totally, the ISC includes seven members. The task of the ISC is to guarantee the smooth operation of the IOI by meeting before each IOI to screen the problem set and test the grading system.

The International Technical Committee (ITC), a long-term standing committee, works with each host country to ensure continuity and quality control of the IOI competition environment (hardware and software). Members of the ITC may not be members of a national delegation. The ITC consists of seven voting members, all of them computer specialists with a background in Olympiad contest systems.

Ceremonies and Other Activities

At the opening and closing ceremonies, the speeches could be given. Usually they are speeches of thanks and summary of the IOI, and finally the host country hands over its responsibilities to the next host. The IFIP greeting belongs to the closing ceremony as well. Entertainment performances have also been very common.

The highlight of the closing ceremony is the awards ceremony. At the IOI the bronze medal is given to one quarter, silver medal for one sixth, and gold medal for one twelfth of all contestants.

The social and cultural program is an integral part of the IOI event. The organizer has an opportunity to show its creativity and make the IOI event memorable. The social and cultural program allows delegates to mix informally and network but also to experience something spectacular from the host country. The local convention bureau, conference offices, travel agencies, etc. are invaluable assistance in planning the social and cultural program.

The IOI program includes 2 leisure days with excursions. The excursions provide unforgettable

experiences for the participants. Nature usually offers many possibilities and every country has its own specialties. Culture has a great role in the social and cultural program. People usually want to experience the culture in one way or another.

Tasks and Evaluation

The purpose of the IOI tasks is to measure the skills of the students in writing effective and correct software code. The IOI tasks must meet several requirements before they can be accepted to be used in the IOI competition. The language must be standard English without any features which can be interpreted as a local expressions or dialects. The task texts cannot be too long because this might cause the student to give up solving the task even if the task itself could be simple. The tasks cannot be derived from any very specific area of the computer science. An important issue is that the tasks should be interesting enough to motivate the student to solve the given task. This also means that at least some part should be relatively easy and some parts relatively difficult. From the organizers' point of view, the task is failed if it produces a big number of zero points or a big number of full marks. Solving tasks should give a realistic evaluation to the students about their skills compared with other students.

The IOI tasks are of algorithmic nature; however, the contestants must show such basic information technology skills as problem analysis, design of algorithms and data structures, programming, and testing.

Tom Verhoeff, one of the leading persons in developing tasks for the IOI, wrote an article analyzing the IOI tasks of the first 20-year history; he summarized task type and difficulty level and classified them according to concepts involved in their problem and solution domain (Verhoeff 2009). Difficulty level is determined based on what percentage of contestants were able to "fully" (a submission should be scored 90% or more) solve the task.

The earliest IOI featured a single task on a single competition day. The next three IOIs each had 2 competition days with a single task, while at

IOI'93 there were three tasks on the first day and only one on the second day. The first 3 years, input-output (I/O) was through a console interface (keyboard and screen) and thereafter through disk files. Grading was done manually by an evaluator who operated the program on the contestant's computer.

At IOI'95, a new kind of task was introduced, referred to as reactive or interactive tasks, as opposed to the "classical" (single-) batch-style tasks. In a batch task, all input data is available at the beginning of the run, and it does not depend on the program's behavior. In a reactive task, some output must be produced before new input becomes available. That input may depend on the preceding output. The program has a dialogue with the (programmed) environment.

Another new type of task was introduced later. They became known as output-only tasks, where the contestants do not submit their programs but only the output files for several given (i.e., non-secret) input files. Of course, creation of the output files requires algorithmic thinking and in most cases also considerable amounts of programming.

Subtasks as a means of offering an opportunity for partial credit came into disuse in the second decennium of IOI.

Test run clustering was introduced at IOI 2005 to reduce the opportunity for harvesting undeserved points by guessing and other forms of opportunistic programming that is not aimed at solving the actual computational task. The points for a cluster of test runs are awarded only if all test runs in the cluster are successful. More generally, the score for a cluster is defined as the minimum of the scores for the constituent test runs.

The use of centralized *Linux* servers for grading was introduced in 2001. This allows better control over resources (time, memory, files, network) used by submitted programs during the evaluation test runs. The contestants submit their work through a web interface to the contest support system, where evaluation takes place.

Russian delegation leaders V. Kiryukhin and S. Okulov (2007) have published a book about all tasks of the first 18 IOIs, including the task descriptions, analyses, solution guidance,

classifications, and pseudo-code and Pascal implementations.

Many of the tasks are too hard to use “as is” in regular CS courses for secondary education. The kind of algorithms that nowadays plays a role at the IOI is too advanced for incorporation in the high school curriculum.

However, in international competitions, testing is the only way the solutions are evaluated. This is mainly due to the multilingual community and a huge amount of solutions to be evaluated in a short period of time.

Testing of batch-type problems involves creating a set of input data cases, running the program submitted by a contestant with those input cases, and then analyzing the obtained outputs. There are some principles used for creating tests. First, various solutions of different efficiencies are analyzed and programmed. Second, tests are generated or manually designed to reflect the efficiency of solutions and the correctness of boundary situations.

The programs submitted in IOIs are evaluated as black boxes. The contestants do not have an opportunity to submit their design ideas to be considered in the evaluation process. If they have a correct but inefficient program, they know it will not give them full marks (maybe 60%).

The programming languages that may be used in the IOI competition are now restricted to Pascal, C/C++, and Java. Pascal will be removed from the list probably by 2019. Python has been a promising candidate during more than 10 years and is still a strong candidate. The challenge in involving new languages in the competition is the amount of labor resources needed to upgrade the competition environment to adapt the new language.

The nature of previous tasks should not constrain the design of new tasks; the submission of novel task types not yet seen in IOIs is encouraged. We are particularly interested in tasks whose basic rules (if not optimal strategy) are accessible to a wide audience and tasks that illustrate algorithms and computational problems that arise in a variety of human endeavors. Open-ended tasks, ones that do not necessarily have a known efficient or optimal solution, are welcome.

Each competitor has her or his own workstation. There is no restriction on the number of times a program may be edited, compiled, and run on the workstation. The workstations have network access to the grading system, as well as facilities such as printing and solution submission.

Grading and evaluation take place on the grading system, which provides a similar execution environment to that of the contestant workstation. Grading workstation will have the same hardware and software configuration as contestant’s workstations (except for programs required for monitoring and grading system).

Nowadays there are a reasonable number of grading systems available for the competition. Sometimes the host country creates its own grading system, and sometimes the system from some earlier IOI is accepted.

The IOI Conference on Olympiads in Informatics

The IOI community consists of over 80 participating countries. We face mainly the same problems: how many of the countries have national Olympiads in informatics? Do they have some other contests on programming? How do we pick our students? How do we train them? The IOI presents an ideal forum for discussing these experiences and associated issues. It was decided to establish conferences during IOIs.

The idea to organize the conference during IOI, when students have solved their tasks, was raised at GA Meeting during IOI 2006. It was decided to send a call for papers, to publish proceedings (a journal *Olympiads in Informatics*), and to run the conference next year. The first IOI conference was held in Zagreb, Croatia, in 2007 during the first and second competition days. The 17 selected papers discussed the running of and issues facing several national Olympiads: Brazilian, Canadian, Chinese, Croatian, German, Italian, Polish, etc.

Next IOI conference was organized in Cairo, Egypt, and it concentrated on training and task types, and many of the ideas and experiences were drawn from the national Olympiads. Tasks are perennial issue for contests, their most visible

aspect, and, for many contestants, the primary reason for participation. The IOI community strives for quality, variety, and suitability. We endeavor to make tasks interesting, understandable, and accessible.

The IOI conferences are followed by the proceedings *Olympiads in Informatics* (2018). It is a refereed scholarly journal that provides an international forum for presenting research and development in teaching and learning informatics through competition. Submissions of papers are flexible, and there are no requirements to participate in the conference while paper is accepted. Now the journal *Olympiads in Informatics* is indexed by Scopus, Inspec, Eric, Era, and other databases.

In 2016, the IOI journal celebrated its 10th year anniversary. This year we have published two volumes, as we are delighted to publish a special volume celebrating the informatics education of our host, Russia Federation.

During the existence of the IOI journal, more than 200 papers were published showcasing 200 authors from 50 countries. Technical papers and country reports, views, and opinions.

Regional and National Olympiads in Informatics

The national Olympiads exist in a wider community – of course, it is also true for the international Olympiads. In order to ensure better preparation for the IOI and to strengthen regional relations, various regional Olympiads are organized. While the national Olympiads represent informatics teaching traditions of each country, the regional Olympiads are usually a mini model of the IOI, allowing the participants to experience what they will come through in the IOI.

The first *Balkan Olympiad in Informatics* (BOI) was for the first time organized in 1993 in Romania and every year thereafter.

The Central European Olympiad in Informatics (CEOI for short) inspired by the fast-growing popularity of the IOI, the Romanian team proposed in 1993 to organize a similar event for the Central European countries (as a matter of fact, they have been organizing the Olympiad in Informatics of the Balkan countries since many years). Shortly thereafter, Romania officially invited the teams of Austria, Croatia, the Czech Republic, Hungary, Poland, Slovakia, and Slovenia to participate in the first Central European Olympiad in Informatics. Five of these eight countries Croatia, the Czech Republic, Hungary, Poland, and Romania sent their teams to Cluj in May 1994 where, upon special invitation, four more teams from Moldavia, Romania, Yugoslavia, and Turkey took also part in the contest. CEOI'94 was hosted by the “Tiberiu Popovic” secondary school in informatics, Cluj; the organizing committees were headed by Ms. Clara Ionescu and Dr. Horia Georgescu (CEOI 2018).

The Baltic Olympiad in Informatics (BOI) was established on the initiative of three Baltic countries (Estonia, Latvia, and Lithuania) in 1995, and few years later, it was opened to all countries around the Baltic Sea (Poranen et al. 2009). The main goals concentrate on providing the participating students with experience of an international Olympiad, encouraging communication and exchange of ideas between the developers of national contests in informatics, as well as assisting delegation leaders in selecting participants for the IOI.

The BOI is a short-term (lasting 3–4 days) and inexpensive event. It can be distinguished for cozy and good neighborly atmosphere, which is highly important when motivating students for self-help.

Even though the BOI is a mini model of the IOI, it has significant differences from the cultural and learning perspectives. The organization of the scientific part of BOIs is based on mutual trust of the participating countries. The leaders of all the participating countries offer problems for the nearest BOI. At first draft task texts are offered, then the ideas are exchanged via e-mail and discussed, and some problems are rejected, while other problems

are suggested to be modified and later are accepted. Most of the problems are translated to the native languages by the leaders before going to the Olympiad. This is a unique possibility for country representatives to gain experience in organizing the scientific part of a small international Olympiad as well as to raise their qualifications in algorithms.

The organizers of BOIs try to follow as close as possible the newest IOI trends in problem types, compilers, platforms, and contest systems. Even though all the tasks are of the algorithmic nature, they represent cultural and methodical differences. Since in the BOI much preparatory work has been done in advance, team leaders can discuss the tasks, possible solutions, and technical issues, and the BOI can be considered as a pre-arranged international way of learning.

The first *Baltic Olympiad in Informatics* was held in 1995 in Tartu, Estonia, with three participating countries. Over the years, BOI has become an established event, and many new countries have joined the contest. 2017 is the first year BOI is held in Norway and the first time Iceland participates.

National Olympiads have more complex infrastructure. Countries have different educational systems, but there are as many similarities as differences. Usually there are several rounds, e.g., school, regional, or state round. It is also common to use difficulty levels, e.g., junior and senior.

More than 40 countries published about their Olympiads in the IOI journal *Olympiads in Informatics*. volume 10 has a special issue focused only on teaching informatics and running contests in Russian Federation, and volume 11 has a special volume devoted mainly to informatics education in Iran.

Conclusions

Computers are becoming more and more frequently used in the education from kindergarten to high school. There is a general worry that all the millions of computers in schools and all the millions of smartphones are not used in a pedagogically meaningful way. Enormous computational power is in the idle mode because the teachers are not aware of the advances of the computer science and pedagogy.

Things can be improved, and in this entry we have emphasized the value of computer programming and attraction of computational thinking to bring a significant improvement in learning and teaching in schools. The success of the IOI and other local computer Olympiads have been very encouraging to really believe that computer programming is one of the tools which make a regular teacher's work more productive and meaningful. It can be seen that in many countries the local and national curriculum renewing initiatives the role of the computer science and computer programming are gaining weight reflecting the increasing demand of computer professionals in the country.

Contests play an important role as a tool of motivation and inspiration. In order to encourage students to learn computer science, we should look for attractive didactic forms. The Olympiad in informatics and the *Bebras* challenge on informatics and computational thinking could serve as useful examples.

Computer Olympiad is a globally recognized way to involve students into informatics and a very important motive to improve their programming skills. There is a steady infrastructure of the IOI. A community of researchers, teachers, and other professionals in education has been formed too. The regional Olympiads are organized following the same principles. Similar Olympiad movements exist in many countries. Various difficulty levels in national Olympiads render a possibility for the students with different experience and knowledge of programming to participate in the event. Even the beginners in programming can acquire motivation to participate and to learn. Olympiads are mainly focused on algorithms design and programming. Actually, tasks are rather difficult for many school students and require continuous efforts.

Let's take Olympiads and contests in informatics as a serious didactical approach of computer science education and support them with learning material, tools, teacher training courses, etc. Olympic and contest communities are open for proposals and ideas for collaboration and future developments. Involving pupils in recognition of informatics as a science discipline should be our target, and we should try to achieve it together. Well-organized contests with interesting, playful, exciting problems and attractive awards will involve school students into the essence of the computer science world and will help to understand the realities, possibilities, and failings of the technology.

International Reports (Including OECD)

Cormac O’Keeffe
INSEEC U., Paris, France

Introduction

Since the 1980s, the production of international reports on education has increased sixfold (see Fig. 1). From a handful of reports published per decade in the second half of the twentieth century, they have rapidly increased in number and gone from reporting on educational attainment from a dozen European countries to over 70 countries and educational systems for test-based reports (NCES 2019). Meta-studies such as the United Nations Educational, Scientific and Cultural Organization’s (UNESCO) Global Education Monitoring Report analyses data (or the absence of) from over 240 countries (UNESCO 2018). Yet despite being a relatively recent phenomenon, international reports on education and the organizations that publish them have become increasingly influential in the economic, political, and professional decision-making processes of governmental educational reform (Hamilton 2017).

These reports can be understood as documents that seek to provide information about national education systems across groups of countries or regions (such as Chinese Taipei, Hong Kong, Belgium Flanders, or Northern Ireland). While they can vary in both form and rationale, most reports serve as policy instruments that place an emphasis on analyzing the differences and similarities found in educational provision and attainment within and across educational systems with an aim to make recommendations that draw upon on these comparisons.

To accomplish this, they describe the characteristics of those organizations that provide schooling and training at the various levels of formal and compulsory education, as well as producing data on the resources, approaches, and strategies employed in each country or region. In addition to measuring characteristics such as access rates and demographic data, the majority of international reports focus on educational attainment, with the primary, tertiary, and post-secondary sectors often receiving the most attention. Since the actors producing these reports seek to either influence national or transnational spending and policy-making within state or international entities, the reports focus almost exclusively on state- or publicly provided educational systems. Education and training offered by privately funded or vocational training sectors receive relatively little in the way of coverage. Although the actors authoring many reports often frame the rationale and findings as being internationally relevant, the analysis and policy recommendations are centered on nation states or individual regions as either partners or competitors in a global economy.

Background

In Europe, many governments, from the late eighteenth century onward, began developing and expanding their national education and vocational training systems. This was in response to changing labor market demands made by state bureaucracies and industries for a workforce that was better educated and trained.

International Reports (Including OECD),

Fig. 1 International reports on education produced between 1959 and 2019. (Source file: intReports60years730x365.eps)

As such, this meant that the need for data on education and training increased, leading to an increase in the demand for reports on the ability of educational systems to respond to these changing demands.

Initially, reports on educational provision and attainment were, for the most part, created and published by national governments using data produced by national statistics agencies or the schools themselves. In the nineteenth century, reports or studies on educational systems tended to be isolated publications with relatively limited influence or institutional support (Cardoso and Steiner-Khamsi 2017). Although the development of standardized indicators against which various educational statistics could be measured (access, gender ratios, teacher pay, graduation rates, etc.) had already been well-established since the nineteenth century, such data production exercises were heavily adapted to institutional, national, or regional contexts with little in the way of coordinated international harmonization or standardization.

Often commissioned on an ad hoc basis, early international reports were typically isolated efforts and not part of coordinated global effort to systematically standardize educational data production for the purposes of policy borrowing or learning. They focused on the international dimension insofar as they sought to modify local conditions within national or regional boundaries and did not aim to affect change or influence education across national or regional boundaries.

International Educational Reporting and ILSAs

The expansion of national education systems during the twentieth century was accompanied by the consolidation of comparative education into a discipline with the creation of journals, international professional societies, and university departments. The University of London's Institute of Education and the Teachers College at Columbia University's International Institute both published educational yearbooks that compiled national reports on educational issues ranging from the church and state to curriculum (Bereday 1957). The years following the Second World War saw an intensification of reporting with the start of UNESCO's *World Survey of Education* (UNESCO 1955). Unlike previous yearbooks or reports, UNESCO's coverage was broader (197 member states) and sought to directly influence policy through the articulation of universal educational goals, such as free and compulsory primary education (King 2016). The trend toward international reports on education that linked global targets and statistics continued in the late 1950s, when members of the United Nations Educational, Scientific and Cultural Organization (UNESCO) began working on what would later become the International Association for the Evaluation of Educational Achievement (IEA).

The IEA's mission was to create a laboratory for investigating for what it termed the "determinants of educational outcomes and comparing

them across nations with the express aim of revealing important relationships that would otherwise escape detection within a single education system” (de Landsheere 1997, p. 1). Where the IEA broke with the tradition of earlier reports was its extensive coordination and organization of international governments and agencies, with the aim of comparing educational practices. Perhaps even more critically, the IEA reinforced and naturalized the close alignment of reporting with educational testing. The IEA created two core assessment activities, Trends in International Mathematics and Science Study (TIMSS) and Progress in International Reading Literacy Study (PIRLS). These international large-scale assessments (ILSAs) produced data on literacy and numeracy levels within national populations that were linked to internationally comparable scales. In moving toward the inclusion of standardized test data into international reports, the IEA also began the work of formalizing and operationalizing the concepts of literacy and numeracy as measurable psychological constructs or skills.

This process of internationalization and standard setting was intensified in the 2000s. Transnational organizations such as the Organisation for Economic Co-operation and Development (OECD), UNESCO, the World Bank, and the European Union (EU) sought to normalize reporting and prioritized international standards that could be “borrowed” by national governments for the purposes of policy decisions (Steiner-Khamsi and Waldow 2012). The EU’s Lisbon Agenda in 2000 reinforced the link between education and the role of indicators in the measurement of lifelong learning outcomes as a measure of economic competitiveness (Ertl 2006). Similarly, in 2015, the inclusion of educational provision and attainment into the United Nation’s sustainable development goals countries receiving financial aid were expected to modify educational provision in alignment with broader economic development targets (UIS 2016). This further strengthened the link between test data and indicators produced by international reports to the funding and accountability measures and gave reports an even greater role as key reference documents in debates and

decision-making regarding educational provision and spending priorities.

At the forefront of this was the OECD. In the 1990s, the OECD began positioning itself as an actor in the production and analysis of educational indicators as a way of measuring a member state’s economic development. In 2000, the Programme for International Student Assessment (PISA) extended the work of the IEA’s test-based reporting to make literacy and numeracy skills that could be measured independently of national or institutional contexts. In doing so, the OECD produced international reports that were less driven by the research-oriented comparative education agenda of the IEA universities but by a political and econometric framework that situated reports as policy instruments that sought to align educational attainment with economic indicators such as gross domestic product (GDP) to measure human capital development. In this way, international reports were able to provide national governments as well as transnational agencies such as the UN, the World Trade Organization (WTO), or the World Bank with data on education that could be measured against other economic indicators.

The OECD intensified test-based reporting by expanding the number of countries with industrialized economies with regular PISA deployments. It also developed the scope of testing and reporting with adult skills’ reports, beginning with the International Adult Literacy Survey that later became the Adult Literacy and Lifeskills Survey with the Programme for the International Assessment of Adult Competencies (PIAAC) extending the range of PISA surveys. Critically, the OECD was able to establish itself as an influential actor in a network of testing agencies (Educational Testing Services, Pearson, Australian Council for Educational Research, IEA) and international organizations (EU, Statistics Canada, UNESCO-UIS) that reformulated educational attainment as human capital, or skills, that could be measured with sophisticated psychometric technologies. As these test-based reports have become increasingly naturalized, the number of countries participating in the data production for reports has also grown (see Fig. 2).

1959–1969

2010–2019

International Reports (Including OECD), Fig. 2 Countries participating in test-based international reports

This move toward a psycho-econometric modelling of education from a socially and culturally situated conceptual framework allowed reports to be used as policy instruments by nations or regions to benchmark their own systems in context, where national education systems competed to be the highest scoring performers in a global knowledge economy. In order to achieve this shift, reports became increasingly statistical in nature and relied heavily on the use of surveys and psychometric educational testing to produce norm-referenced assessment data. The move toward data-driven and technocratic reports gradually superseded humanist and emancipatory discourse of UNESCO's Faure (1972) and Delors (1998) reports on international education. As a result, international reports on education are now almost indissociable from ILSA-based reports that formulate educational attainment, chiefly as skills acquisition. ILSAs focus on the role that education has to play in the production of data on internationally comparable skills as proxy measures for economic competitiveness. This narrative has come to dominate the rationale for reporting on education and led to the marginalization of reports that emphasize cultural differences and non-economistic goals (Addey et al. 2017).

Digital Technologies and International Reports

A more recent trend in the development of international reports has been the increased use

of and exploration of uses of digital technologies. From the initial stages of data production and analysis, to the eventual publication and communication of the findings, digital technologies have played an increasingly significant role in transforming the character and reach of international reports on education.

The OECD's PIAAC, published in 2012, was the first report to rely almost exclusively on a digital test and survey tool for its core data production and analysis (OECD 2013). Although PISA 2006 used computers to test science skills, PIAAC was an important test case for the use of digital technologies for the automation of data production. With its successful implementation, PISA 2015 and PIRLS 2016 (or ePIRLS) have also been digitalized with all subsequent deployments of these reports, with certain exceptions, following this trend. The move away from traditional "paper and pen" or printed approaches for the data production of international reports has happened for several reasons.

First, since students are interviewed and tested using digital devices such as tablets or laptops, sampling accuracy, data security, integrity, and transfer to data storage are easier to control. As much of the data are drawn from cognitive tests, personality surveys, or background questionnaires, digital technologies are able to process and score results with greater precision and rapidity and greatly reduce human error or falsified data. Furthermore, digital tests are able to apply sophisticated algorithms that select and adapt test and survey

questions with speeds and agility unmatched by a human being. These algorithms, by adapting to a respondent's answers or background variables – such as educational level, cognitive test scores, nationality, and so on – allow test makers to reduce inaccurate results caused by test fatigue as well as increase the scope of the domains tested and the populations sampled.

Measuring Digital Skills

One of the more novel aspects of the digitalization of international reports is the role it plays in innovating in the type of data that can be produced and reported on. Tests such as PIAAC began expanding the range of concepts to be measured by introducing a test called Problem Solving in Technology Rich Environments (PSTRE) to evaluate the digital skills of workers in OECD economies. Similarly, PISA 2015 and ePIRLS used items that tested the ability of school-age children on their ability to retrieve and process information found in digital environments, such as websites or digital documents. In many ways, the digitalization of report data production is a consequence of the world that the reports describe. PISA 2018's objective is to report to what extent children have “global competence” or the ability to understand and engage in local, global, and intercultural issues. To do this, students are tested on their ability to capitalize on digital spaces and use online media to communicate with others. As with PIAAC's PSTRE evaluation, the inclusion of digital skills in international reports is a response to concerns about a “digital skills gap” or the belief that adults and children lack the skills to navigate a world where being able to use digital technologies is portrayed as being indispensable to participating in society. These tests all attempt to measure, albeit in standardized simulations, “real-world” problems that can be used to report on real-world skill deficits or abundance. These data are then used to translate the performance of the “right skills” in tests into economic indicators. This in turn provides evidence that can be used in international reports that are oriented toward analyzing the relationship between both schooling

and higher education and the ability of citizens to participate in “an increasingly digital and globalised world and for countries to promote inclusive labour markets and to spur innovation, productivity and growth” (OECD 2016b).

Third, the move toward asynchronous and remote testing that requires minimal or no human supervision and dispenses with the time-consuming and complicated spatio-material configuration of schools and equipment allows international agencies to increase number of educational providers contributing data by reducing participation costs through digital delivery. As such, the “dematerialization” of international reports has led to the development of micro-ILSAs. These tests are smaller versions of the main tests but draw extensively from the same statistical, conceptual, and operational technologies. Unlike ILSAs that are performed at a ministerial level, these micro-ILSAs are testing and reporting tools that are pay-per-use and deployed on demand by whichever entity meets the technical and financial prerequisites. The OECD's PISA for schools, like the main test, produces data and reports on 15-year-old school students but differs significantly in some key ways. PISA for schools allows schools to generate their own reports and data on an individual student's ability and thus moves away from the logic of anonymized low-stakes testing for individuals. Unlike the main test, it also encourages schools to use the data produced in the reports to implement curriculum change and classroom practice. Furthermore, the test gives access to an online platform that allows schools to compare results with other schools and countries and engage in school-level policy borrowing and learning. That is, schools can choose the features of the other educational systems that have higher test results and use or “borrow” educational practices to change local-level school policy (Lingard 2010) and align themselves to international practices. ESONline, a pay-per-use version of PIAAC developed by the OECD and the EU, performs a similar role for prisons, research centers, refugee centers, or private companies that wish to produce reports that measure the skill levels of targeted adult populations (OECD 2016a). These reporting tools, deployed outside of the regular 3-year cycles

of the main tests, allow participating schools and organizations to link their customized reports to international benchmarks, standards, and results. They also provide the OECD and its partner organizations with an almost entirely automated flow of data allowing it to refine and adapt its psychometric and economic models of education.

Digital Publication of International Reports and Datasets

The digitalization of reporting is perhaps more obvious in report publication. International organizations have recently been complementing the more traditional book format of reports by investing in websites where data on indicators are continually updated and accompanied by data displays and visualizations that facilitate dissemination by the media and governments. The World Bank's Education Statistics (World Bank 2018) website aggregates data produced by UNESCO's Institute of Statistics (UIS) (UIS-UNESCO 2018), the IEA, and the OECD. Rather than waiting for the publication of a report, visitors can consult data tables, maps, and displays on learning outcomes, educational attainment, quality, expenditures, and policy. The OECD's Education Global Positioning System (GPS) (OECD 2018) provides similar data explorers that generate data visualizations that rank countries on their international performance. In addition to the graphical representations of educational indicators, both organizations allow visitors to download datasets. Although some data are relatively simple to read and available in spreadsheet form, most of the educational data found in reports require the use of specialized statistical software such as the Statistical Package for the Social Sciences (SPSS) in conjunction with the IEA's *International Database Analyzer* software package (IEA 2014). These datasets, primarily intended for use by researchers, government employees, or journalists, extend the scope of reports on educational system planning and policy by the use of these data in articles, whitepapers, and scholarly publications.

Conclusion

Due to the considerable time, expense and expertise demanded from the network of scientific, business, and governmental actors required to produce international reports on education, a relatively small group of actors are involved in their production. These are, unsurprisingly, international or transnational organizations such as the OECD, UNESCO, the EC, the World Bank, and the IEA, whose reporting activities are financed and commissioned by the national governments that fund them. A notable exception to this is the McKinsey Consulting Group that produces independent international reports on education. Even so, in recent years, the OECD and IEA have acquired a quasi-monopoly on test data-based reports. The UIS's Literacy Assessment And Monitoring Programme (LAMP) which aimed to produce IALS-like data for developing countries from 2003–2011 has been discontinued and replaced with survey data. The World Bank's Skills Toward Employability and Productivity (STEP) test that measured and reported on workforce competencies and skills acquisition in 2010 has never seen subsequent iterations. The World Bank now draws extensively upon OECD and IEA data for educational or human capital reporting.

However, since the creation of reports is concentrated in the hands of a relatively small number of organizations, however large in size, a certain consensus on how to understand educational attainment and intervention has evolved. This can be characterized in a number of ways. First, skills and outcome-based education is seen less as an emancipatory process than as an economic one. That is, investments into education and training are seen as inputs that produce different levels of human capital and as such increase or decrease a nation state's economic competitiveness and capability to innovate and produce. Alternative visions of how to report on education, such as the UNESCO's Global Education Monitoring (GEM) Report, are less focused on tracking skills levels than engaging with specific themes such as migration, the environment, conflict, inclusion, or other issues to ensure that the right to education is achievable.

Although these reports influence policy decisions, particularly in regard to sustainable development goals for education, they do not have the same weight in political discourse and in media representations as test-based reports. The GEM reports lack the affective force or “shock factor” of the statistical educational league tables produced by test-based reports that frame education as a crisis and, as such, they lack the same impact and ability to act as agents of policy change.

The last 30 years has seen international test-based reporting grow in influence. However, this kind of reporting has certain limitations. Part of the success of this style of reporting is in its ability to produce quantitative and standardized data on educational outcomes. In this way, it is part of an already well-established project of government and private actors to produce and leverage quantitative data on many aspects of citizens’ lives beyond education. However, this is also one of its limitations, as seen in the OECD’s failed attempt to extend this style of reporting to the higher education sector with Assessment of Learning Outcomes in Higher Education (AHELO) in 2012. The ability to report on sophisticated skills and knowledge is not something that large-scale tests can do easily – spoken and written production are all absent from such international scale reports into education. Similarly, international reporting can ignore or have difficulty integrating the role of local histories and cultures that can be important determinants of successful educational outcomes. The “culture-free” dimension of international reports has often led to failed or counterproductive policy borrowing. Nevertheless, with the intensification, digitalization, and ubiquity of quantitative data production, the statistical and test-driven character of international reports on education looks to have a stable future in the years to come.

IT in Educational Institutions, Planning and Development of

Jorge Rodríguez-Díaz
Universidad de Las Palmas de Gran Canaria,
Las Palmas de Gran Canaria, Spain

Definition

Planning and development of information technology (IT) in educational institutions consists of a set of activities aimed at identifying what the future information architecture of an education center should be. During this process, the IT applications that can most effectively contribute to the achievement of the center's mission and objectives are identified; the order in which the candidate applications are developed is also

prioritized, and the volume of investment in them is decided, as well as the most appropriate development methodology to ensure the success of the project.

Introduction

There are numerous evidences that demonstrate the need to carry out organized processes of IT planning and development in organizations (Marabelli and Galliers 2017; Kumar 2015). Sometimes this process is not carried out in an orderly manner; money is invested in technology to solve specific problems that may not be useful in the long term for responding to information needs. In addition, the disorganized implementation of IT can lead to problems of duplication, incompatibility, and premature technology obsolescence (Kumar 2015). Education centers represent a type of organization in which there is a need to carry out organized IT planning and development processes. This need is the result of a series of characteristics, including (a) the handling of a large amount of teaching, administrative, and personal information, which obliges them to comply with requirements related to privacy and ethics in the use of the IT; (b) limited economic resources, which implies the need to rationalize investments, including in technology; and (c) although a large number of education centers are not run for business purposes, they nevertheless do play an important social role and have a mission and objectives to fulfill.

To this, we must add the varying nature of the educational training offered according to the type of center. Schools and high schools share a similar mission, fundamentally based on the teaching of concepts, although with different methodologies according to the age of the students. Vocational training centers have, basically, a “professionalizing” mission, based mainly on a practical education oriented toward training professionals who will mostly perform “blue-collar” type jobs. Universities and colleges share a professionalizing and research mission, where theoretical and practical training is combined, oriented fundamentally toward training professionals who will mostly take up professions of the “white-collar”

variety. This different conceptualization of education centers adds a challenge when establishing IT planning and development processes.

Another factor of added complexity is the low level of familiarity of many educational managers with IT. This fact means that, frequently, the function of coordinating the planning and development of IT is delegated to third parties (Marabelli and Galliers 2017). In this way, the overall vision regarding the direction of education centers is lost, and the planning and development of IT is a poorly organized process, even, at times, chaotic. This multidimensional problem hinders the proposal of an integrating model for the planning and development of IT in educational institutions. The availability of a conceptual framework that guides this type of process could be very useful for educational managers in facing this type of challenge with certain guarantees of success.

The field of education can benefit from techniques and tools related to the planning and development of IT that have been widely verified in other organizations. The accumulated experience in this area by many education centers, especially universities, can also be taken advantage of. The greater relative size of universities has meant that, for decades, they have had experience in the problem of IT implementation. In order to provide an integrative proposal for the planning and development of IT in education centers, a broadly verified and simple approach is presented below. The proposal is based on an information architecture planning model rooted in IT application portfolio matrices. This model is characterized by a broad capacity to adapt to different situations and scenarios, having demonstrated its practical usefulness. This is due, in large part, to the extensive experience accumulated over time of its use in all types of organizations. In the following sections, the proposed approach will be described, and it will be particularized for different educational levels.

Information Architecture and Planning

Planning, simply put, is deciding what to do before taking any action (Reynolds 1992). An IT

plan is needed to guide all economic, human, and material efforts to achieve effective information management in an organization. The IT plan defines what projects to develop and at what time. It also serves as a reference to justify the use of scarce resources at an organization. The existence of an IT plan can even serve as an argument to help management stop a project already under way if the project is not consistent with the overall plan (Reynolds 1992). In organizations, as in education centers, the IT plan must be consistent with the mission, objectives, and maturity of its IT infrastructure. A first requirement for a successful plan is that the participants agree on the scope, deadlines, and expected results (Peppard et al. 2014). In the educational arena, the center's management team is responsible for establishing these parameters, alone or in cooperation with other agents or advisors, both internal and external, to support the planning process. In this part, it is very useful to establish the reasons that justify the development of an IT plan. Among these reasons may be dissatisfaction with the current management of information at the center, a change in the mission or its objectives, the updating of a previous IT plan, etc. Another relevant factor that justifies IT planning is the identification of trends in the educational field and in technology to support the teaching-learning and data management processes (student records, academic performance records, etc.). Understanding the changes that are taking place in the education sector and how they can affect educational institutions may be the key for the plan to be able to respond to challenges in the environment. The IT plan must explicitly incorporate how to respond to these identified external trends.

The IT plan should also consider the current situation of the education center in terms of IT infrastructure and maturity in the use of said infrastructure. The degree of response to external IT challenges will depend on the level of internal development. For this reason, the proposals emanating from the plan must be realistic and coherent with the current situation of the center. If the degree of development and maturity of IT does not allow an immediate response to trends in the educational environment, then this fact should be

considered in the plan. In this case, it would be necessary to establish actions to cover this gap between the internal situation and the challenges that are to be faced or to reformulate the objectives of the IT plan. From the conjunction of the elements that converge at the education center (mission, objectives, trends in the educational environment, IT situation, etc.), a set of potential IT projects will arise that will constitute their future information architecture (Chan and Reich 2007; Ward et al. 1990).

The architecture of applications is a table that aims to reflect and classify the applications that must be developed or improved according to the information needs of an organization. A useful way to represent the information architecture is through the concept of an application portfolio matrix. Each IT application can be positioned in the cell of an array according to its potential contribution to the organization. The advantage of this approach is that, according to the cell occupied by the application, there are generic recommendations that can be helpful in making decisions about IT. These may be decisions of the following type: (a) relative volume of investment, (b) priority in the order of development of the IT applications, (c) method for the development of the application, (d) more appropriate information technology, and (e) form of IT management once it is operational. Despite the utility that these tools can offer, it is necessary that their adoption be carried out with caution, since what is offered are generic recommendations. However, it cannot be forgotten that it is necessary in each specific case to evaluate the different alternatives and carefully study the implications of the decisions to be made.

Application Portfolio Matrices

As a result of IT planning, it may be concluded that there are several IT applications that should be carried out to cover current and future needs. If the education center has a strong innovative vocation and uses IT as a strategic instrument in its operation, then the number of resulting applications may be high. At this point, the problem of limited

resources arises, which forces management teams to select applications based on their usefulness, associated costs, capacity, etc. There are many variables involved that complicate the process of deciding which applications will be given the time and resources needed to develop them and which others should wait, or even be discarded. To try to facilitate this decision process, the application portfolio matrices have been designed. Basically, they are two-dimensional matrices in which, depending on two simple variables or two aggregate variables (the latter resulting from the weighted combination of several simple variables), the computer application is located in a quadrant of the matrix according to the score it achieves in relation to the defined variables. Depending on this position, experience has allowed the development of generic recommendations that may be applicable for each case. The advantage of application portfolios lies in their apparent simplicity and the capacity for systematization they offer, based on well-defined significant variables. Their usefulness is evident in facilitating what in principle constitutes a task of rationalization and complex decision-making, and that can have strong repercussions for the organization (Tukana and Weber 1996).

One of the matrices of the application portfolio that has most proven its usefulness in facilitating decision-making in IT is the one developed by McFarlan et al. (1983) and adapted by Ward et al. (1990) and other authors (e.g. Wijaya 2016) (Fig. 1). This matrix has as its main feature the fact that it links IT applications with the contribution they make to the functioning of the organization – that is, technical aspects are combined with others of an organizational nature. This ensures a basic premise that should guide any process of IT planning in organizations, which is that utility should always prevail in terms of organization or, to put it another way, technology is only a means to an end. The above is also applicable to education centers, where objectives related to improving the teaching-learning processes and the management of academic and personal data must prevail over purely technological considerations. In the educational environment, the application portfolio matrix allows IT applications to be located on

the basis of the present contribution they may have for carrying out activities and the future contribution that can be expected in a given time horizon (Wijaya 2016). Using both variables, the different IT applications can be located in one of the four cells that it incorporates. Each of the quadrants in the matrix is given a denomination in order to designate the applications that fall within its category. These denominations are the following:

- *Support*. Applications that improve administration and results but are not critical for the organization, since it could carry out its activities almost normally in the event that these applications were not available. Basically, these are applications that facilitate or speed up tasks, generally from a purely operational point of view.
- *Factory*. This group includes those applications that are essential for performing the operations of the organization. They are so important that they have become critical and the organization would encounter serious difficulties if the application stopped working, even for a small period, or if anomalies were detected that made the validity of the information doubtful.
- *Strategic*. These are critical applications for future success and of great importance in the present. It could be that the organization already had some IT application in this group, but it is usually foreseeable that the application will take another form in the future or that it will be presented in a format that also includes other functions or technical advances that make it more versatile and important.
- *High potential*. Applications that may be of future strategic importance, but that currently do not have enough importance to support the activities of the organization. In short, these are potential developments with a high level of uncertainty, since their justification is based on the contribution that could be made in the long term.

Below are generic considerations associated with IT applications according to the cell of the

IT in Educational Institutions, Planning and Development of,

Fig. 1 Application portfolio matrix. (Source: McFarlan et al. (1983) and Ward et al. (1990))

FUTURE CONTRIBUTION

High	Strategic	High potential
Low	Factory	Support
	High	Low

PRESENT CONTRIBUTION

application portfolio matrix adapted to the field of education:

- *Support applications.* Within this category, all the applications that are important for the operation and administration of education centers are framed, although they are not critical because they could continue their operation for a long period of time without them. The second characteristic of these applications is that they are often applications common to all educational centers, so that there can be hardly any differentiation based on the use of this type of application.
 - *Software packages.* Due to the general nature of the activities to be supported, there are many software packages available on the market that can serve this purpose. It is convenient to select applications with a well-established client base that have already been tested, avoiding being the first to use an application.
 - *Functional complexity.* The support applications are characterized by being easy to use because they usually work in isolation, so that an error in one of them does not affect the rest of the IT applications at the center.
 - *Skills.* As these types of applications are usually based on a standard software package, it is not generally necessary to possess high levels of technical skill for their use.
 - *Computational capacity.* The need, in terms of capacity, of most support applications is, in general, completely predictable, which makes it difficult for computer equipment to crash due to inefficiencies in processing capacity.
- *Risk.* With this type of application, no kind of technical risk should be introduced. The software/hardware used may be something new for the center, but it must not be new for the supplier, who must be prepared to deal with any possible incident.
- *Divestment.* These systems, because they are not critical to the center, are candidates for elimination. There may be arguments that justify the subcontracting of this kind of system operation to third parties, in the form of outsourcing, which are advisable to consider.
- *Factory applications.* These applications are vital for the present functioning of the education center.
 - *Software packages.* The factory applications are usually specific to the sector of activity, and even specific to the education center (e.g., college or university) based on the way in which activities are carried out. Although there are standard packages, they are fewer in number and more specific than those available for support-type tasks. Because the integration of data is a key aspect in factory systems, the databases from which they are fed must be highly consistent.
 - *Functional complexity.* Factory applications tend to be functionally complex; they are characterized by having dependencies on other programs, in such a way that any change can affect other applications in

domino effect. If standard computer packages are used and modifications are made to adapt them to the specific needs of the education center, it is necessary to thoroughly check the changes so that the system works and no failures appear.

- *Skills.* This class of application will require modifications to meet the changing needs that may arise at educational institutions. Therefore, a high level of skill will be required by the technical support managers. In this sense, updates to the program are very important and have to be verified and evaluated after introduction. The people responsible for adaptation, whether they are internal or external to the center, must be highly qualified.
- *Computational capacity.* The availability of the system is critical; this means having an up-to-date backup and all the essential components, both hardware and software, should be duplicated or ready to be replaced quickly if problems arise. Capacity planning should be based on peak loads that ensure the response of the system, even in extreme conditions.
- *Risk.* It is important that these systems do not fail; one way to reduce unnecessary risks is to avoid technological innovation in the area of factory applications. The general rule should be to make changes in the technology used only if it has been extensively tested. In case of use of a new IT application that replaces the previous one, the operation of both systems should be carried out in parallel for a time to ensure that the new system works satisfactorily.
- *Strategic systems.* They are those that should allow the education center to stand out in some way over others. It is likely to mean a change in the way the center is operated or controlled. It can also happen that the advantages are not lasting and that, in addition, the application needs continuous improvements to allow it to continue gaining advantage in the future, which brings with it a great deal of expense. Many aspects of technology management associated with strategic systems are very

similar to factory applications, although the biggest difference lies in the need to take risks.

- *Software packages.* It is unlikely that commercial software packages exist for this type of application. If they did, a short-lived advantage could possibly be achieved by being the first user of the package (the sustained advantage comes from the unique character of the IT application, which others cannot easily copy or improve).
- *Functional complexity.* It is likely that these systems are complex or become complex as functions are added to them. Ideally, the system should be tested to ensure the tightness of the risk before implementing it at the operational level.
- *Skills.* Considerable technical and organizational skills are required for its development and implementation. It is important that there is continuity with the members of the technical team in order to conserve knowledge about the mode of operation of the application, given that this context does not facilitate the generation of exhaustive documentation on how to operate it.
- *Data sources and dependence on other systems.* The data in the strategic applications need to be integrated with other systems at the center; they can also take data from external sources. Sometimes, strategic systems are based on existing applications, such as factory or support types. It is important that these last ones are stable and robust applications because, if, on the contrary, they are unstable, the new strategic applications will inevitably expose those weaknesses and cause the systems to crash.
- *Computational capacity.* In direct contrast to factory and support applications, the computational capacity requirements for strategic applications are often very difficult to determine. Therefore, it is advisable to use equipment that allows an increase in capacity or technological updating.
- *Risk.* The projects included in this category are clearly high risk; this is due to the direct relationship between risk and potential

benefits. The risks involved are of a technical or organizational nature, due to the fact that the center may be entering into new, less experienced technological areas, and also in combination with relatively significant changes in working methods (of students, teaching or administration staff).

- *Implications for planning.* A continually updated knowledge about IT trends in the education sector is important to avoid being surprised by other innovative centers. It is also important to develop these applications quickly because the possibility of achieving advantages can be fleeting or short-lived.
- *High potential applications.* They are innovative applications that, eventually, could be of great future importance. An application should only be in this part of the matrix for a limited period until its future is clarified. To facilitate their development and management, the most appropriate course of action is to select a project leader (some member of the teaching or administrative staff), supported by the center's management and with sufficient technical skills to work in a close relationship with the technicians. Before a technology "abandons" the high potential cell, any error or failure should be completely corrected, given the risk that a failure will drag down the rest of the applications. If the education center wishes to stand out from others, it should consider investing in this type of IT application, since if it does not act in this way, it runs the risk that the possibilities to stand out for its IT are limited by a set of outdated technologies and skills.
- *Software packages.* The computer applications that can be found on the market correspond to very novel systems that have not yet been exploited commercially on a large scale, so there is the possibility of obtaining advantages derived from being the first to use this technology.
- *Functional complexity.* These applications have a high level of complexity because they normally support processes whose difficulty in automating has usually been the reason underlying the absence of computer applications to carry them out or because of

new technology that, due to lack of operational knowledge, is often difficult to assimilate.

- *Skills.* Given their innovative nature, these applications require highly qualified personnel, which means updating the training of the center's staff or hiring the support services of leading technology companies.
- *Computational capacity.* It is difficult to identify what will be the capacity needed for the high potential infrastructure, since there is doubt as to whether the applications will be useful for the center in the future or, on the contrary, they will be abandoned. For this reason, it is convenient to use incremental technology, which can be adapted to future growth of the system as the demand for use in the center increases.
- *Risk.* These applications, by their very nature, are of high risk, so it must be assumed as natural that technical glitches and crashes occur, although this should not affect the operation of the educational institutions. That is, the risks should only affect the system under test, keeping it insulated as much as possible from other applications of common use.

Administration (Investment and Priorities) and Development of IT Applications

Decisions about what amounts to invest in IT infrastructure or what should be purchased first can be difficult to make and even become a source of conflict if there is no well-founded justification to support them. In addition, there is the condition of the low level of funding that usually characterizes educational institutions. Numerous techniques offer a reference on which investment decisions to argue for, although it is true that they are mostly oriented to users well versed in technical-financial concepts. This complexity often results in the management of education centers, for lack of knowledge of IT, preferring to leave the IT investment chapter in the hands of third parties, sometimes even external to the

center. For this reason, it is convenient to offer tools that, although they do not have a high level of mathematical rigor, are sufficiently valid and, above all, intuitive enough to allow this process to be led by the center's management.

Investment in IT infrastructure competes with other alternative investments, such as in real estate (new or renovations), equipment for classrooms or laboratories, office supplies, hiring teaching or administrative staff, etc. It is necessary, therefore, to establish a basis on which to evaluate IT investments. Investments in IT in the educational field should not be considered only based on the argument for the benefits that are going to be generated, which are usually very difficult to quantify, but on how they can serve to support the functions of the education center.

The application portfolio matrix provides a support framework for recommending generic guidelines for action on investments and priorities, in which the justification for developing an IT application and investing funds in it depends on the matrix cell in which it is located. This portfolio approach implies that the quantitative justification of the applications is easier in the *support* and *factory* quadrants, while for the *strategic* and *high potential* cells, the justification must be based more on qualitative considerations related to the future objectives of the center. Below is a set of recommendations for which is the most appropriate cost-benefit evaluation system for each case.

- *Support applications.* The main reason for its existence is the improvement of efficiency, which should be quantifiable and become a financial argument for investments. If the application contends with others for the limited resources available, then a supporting application must show a good economic return for the allocation of scarce resources. However, if IT investment capacity exists in a decentralized manner, the corresponding department of the center can assume responsibility for the investment in an application of this type.
- *Factory applications.* As for support systems, it is recommended that benefits (tangible and intangible) or costs be estimated before allocating any resource. In general, a feasibility

study is appropriate in order to find the best solution among a range of alternatives, each with different costs, risks, and benefits. However, some forethought must be demonstrated with the results because this may be inappropriate for factory applications, where the most economical solution may not be the most effective.

- *Strategic applications.* The fact that an application is considered strategic implies that it is considered important, even essential, for the achievement of the center's objectives, especially in the long term. With this type of application, the benefits have to be estimated approximately because it is difficult to adapt an estimate based on the calculation of benefits and costs that can be generated. Therefore, an application will receive the approval (or not) to be developed based on the decision of whether it is relevant to the objectives of the center. The key aspect is whether the management judges the investment as appropriate. In this sense, the critical factor is to allocate resources enough to carry out the development and achieve the objectives within the appropriate time horizon.
- *High potential applications.* The main essence of high potential projects is that the benefits are unknown, the objective being to identify the potentially achievable benefits. It is the R&D segment of the matrix and should be justified on the same basis as any other R&D development. This case is especially applicable to colleges and universities. When the allocations are made, the subsequent sums invested must again be justified and not simply assigned with the vague hope of eventual success. In general terms, investments in IT should be as objectively and subjectively considered as the center's other investments.

Once the evaluation of the likely costs and benefits associated with the applications susceptible to being developed or improved is made, it is necessary to establish priorities between applications when, for reasons of limited resources, not all can be installed at the same time. It is important to introduce a consistent and rational approach to the establishment of priorities if a successful implementation is desired. This is because if

priorities are based on changing and temporary aspects, planning will be meaningless. Using the approximation of the application portfolio matrix, the following conclusions can be drawn:

- *Support applications.* The establishment of priorities is fundamentally based on the fact that those with the greatest benefits (teaching, administrative) that use the fewest resources should have the highest priority.
 - *Factory applications.* The arguments for the assignment of priorities include (a) improvement of the teaching-learning process, (b) improvement of administrative processes, (c) improvement of IT infrastructure, and (d) others. Each of these aspects must be assigned some form of relative weighting so that an order of preference can be decided.
 - *Strategic applications.* Within this segment, the rational basis is based on prioritizing those applications that contribute most toward making the education center stand out from others and, in addition, require fewer resources to develop.
 - *High potential applications.* They are difficult to prioritize and will tend to be decided on, to some extent, unlike strategic applications (what resource is available, and then which IT application could make best use of that resource?). The results will depend not only on the value of the idea but also on the strength with which it is supported.
- As can be deduced from the methodological framework described above, decisions on investment and the priorities for the development of IT in education centers should not be made independently of the mission and objectives of the center, or only on a technical basis, but as part of a wider process. This process should also consider resources, skills, time, risks, etc., and also the correct choice of the development method to be used. In this sense, the principles underlying the classification of the application portfolio matrix are useful for selecting the development approaches. The recommendations for the four categories of the portfolio would be (Ward et al. 1990):
- *Support applications.* Largely, they consist of legally necessary applications, office applications, and personal support systems. They have value for the center, but they are not fundamental for its operation. The most appropriate solution is the purchase of a widely verified standard package that best meets the requirements of the center or that can be conveniently parameterized to fit work habits.
 - *Factory applications.* They are critical for maintaining day-to-day operations, and if they fail, the center can face serious problems. They are, generally, the workhorses, and they need to be well designed, efficient, and robust. The traditional method of development, based on the systems development life cycle (SDLC), is configured as the most appropriate in this segment. It can also be useful to buy a standard program from a recognized manufacturer, and it is essential that the application is not closed but can be parameterized in some of its functions to adapt to the needs of the center. Being applications that are important for the center, although not strategic in terms of being able to stand out in the future, completely outsourcing their development is also possible.
 - *Strategic applications.* They are vital for the future operation of the center and constitute a part of its long-term objectives. Traditional development methods are not usually appropriate in this segment, since speed and flexibility are essential, and effectiveness is more important than efficiency. The best way to develop them is through the close association between users (preferably at the level of center managers) and highly experienced IT analysts/computer programmers. The information content of the service is generally crucial in strategic systems. Therefore, easy access to relevant information is very important. In summary, for this type of application, the most appropriate form of development is the systems development life cycle (SDLC), but using computer tools to support the development itself, commonly known as CASE (computer-aided software engineering).
 - *High potential applications.* They are associated with the R&D category, where the most

innovative technology can be tested to find out its potential contribution to the center's objectives. In this case, a fast and independent development, which can be abandoned at any time, is necessary. Because the risk is high, stringent cost control is essential. The IT applications in this quadrant can be developed by a user, or by a user and a computer professional jointly, analyzing and programming the application. It is important not to risk the functioning of current systems, controlling the effectiveness of experimentation. The most appropriate development approach, in principle, is that of the prototype or the development by users, through the use of fourth- or fifth-generation languages.

Legacy Systems

Most education centers rely on legacy systems for most of their information management needs. Normally these systems offer reliable services, given that, predictably, the failures detected during their implementation were corrected years ago. The main problem with older systems is that they were developed to function in circumstances different from those of the present and have to be updated to meet current and future needs. This circumstance – the reliability of the system, but its low adaptation to new technological trends – means that it may be more profitable to make modifications to the current system than to replace it with a new one. This decision must be evaluated against the cost involved, since some older systems may be expensive to maintain or problems may arise because they operate on hardware or operating systems that no longer have technical support. These variables must be taken into consideration when reviewing the portfolio of existing systems. To summarize, if a legacy system can provide useful functionality in a cost-effective way, then it must continue to be used. In this case, it is convenient to focus this analysis on the future benefits that the system will provide, without considering the costs of the past. With this approach, continued investment in old systems is avoided, however expensive their development

and maintenance may have been, so that the anchoring effect is canceled out by the investment made. In these cases, substitution may be the only viable option for the future.

Schools and High Schools

Schools and high schools are the education centers at which the students attend compulsory education in most of the countries around the globe. Although they offer training at two different levels, primary and secondary education, they have numerous characteristics in common. That being the case, the IT infrastructure shares characteristics and objectives, being a useful tool both for the training of students and for the administrative management of the center (Gulbahar 2007). Normally, these centers do not have specific IT staff, IT support services being, in some cases, outsourced to local supplier companies and, in others, provided by centralized education authorities that serve the schools of a geographical area. At these levels, IT is not only treated as a support for teaching-learning and administrative management but also learning in the management of IT tools – mainly those related to office automation (word processors, spreadsheets, presentations) – and also for the programming of simple codes. The representation of the architecture of applications through the portfolio matrices constitutes a static photograph of a specific moment. As IT evolves continuously, the portfolio matrix also evolves as the new technology becomes ubiquitous. IT applications that are in the *high potential* cell at a given time may, after a time, enter, for example, the *support* category. For this reason, the planning process must be dynamic, and the architecture of IT applications must evolve along with the technology and the maturity of students, teachers, and administrators in the use of it.

Figure 2 shows a proposal for the positioning of the IT infrastructure in the application portfolio matrix in schools and high schools (the proposed structure is far from being normative and only aims to offer an approximation to the possible classification of the IT infrastructure through this tool). Each center can configure the location of

their applications according to their particular situation. In this way, its application architecture would be generated.

Universities and Colleges

Higher education centers have the mission of training in skills for professional and research activity. Their students are adults who choose these courses of study because of their interest in following a path toward a particular vocation. They usually present complex structures, with a large number of students, professors, administration staff, and service personnel (maintenance, security, etc.), distributed across various buildings or campuses in which different undergraduate and postgraduate courses are run and research is carried out. For this reason, it is easy to deduce that IT planning and development is a complex task that requires high levels of investment (Lin et al. 2012). Universities have their own IT support services, which can be centralized for the whole institution or decentralized across different

buildings or functional units. Regardless of the existence of an IT manager, strategic IT decisions should always be the responsibility of the rector of the university.

Figure 3 shows an example of a type of application architecture by means of a portfolio matrix for a university or college. It should be noted that due to the complexity of these types of center, the configuration can change depending on the planning and development of IT from the university level, in general, or the centers that comprise it. Therefore, it is a description by way of example that aims to reflect the different classifications that IT applications may have in this context. However, it can be observed the high degree of coincidence between the potential information architecture in a higher education center and in a compulsory education center.

Summary

Most education centers have information technology and communications infrastructure. In many

IT in Educational Institutions, Planning and Development of,

FACTORY	SUPPORT

cases, this has been installed to respond to particular problems related to the teaching or administration of the centers. The most common situation is that the implementation of the IT infrastructure has not obeyed any particular plan and different agents have been involved in its development, and it has often been done in different ways. IT evolves continuously and leads to the creation of new expectations by its users, which is also true in the field of education. IT has acquired a major role in education centers at all levels, mainly in administrative tasks and as support for teaching. However, the lack of long-term planning can lead to the situation whereby the IT infrastructure available in educational institutions is a burden rather than a driver of change. Within the set of functions of the current crop of education managers is to establish action plans in the field of IT infrastructure. However, the fact that a large number of education managers do not have specialized IT training, along with the limited resources usually available to educational institutions, means that IT planning and development is secondary.

In this entry, an integrating as well as a simple to operationalize framework has been proposed to guide the planning and development processes of IT in all types of education centers. It is based on a widely verified tool in the scientific literature – namely, portfolio matrices. With the proposed model, a framework is offered to guide investment decisions, priorities, and forms of IT development in centers operating at different educational levels.

Introduction

Nowadays, technology is an essential component in our society. Considering its impact in the educational system, Information Technology (IT) cannot be dissociated from the educational process and from pedagogical practices. The role of technology is so essential in our lives today that it is necessary that students develop organizational, problem-solving, and critical skills to meet the demands of an increasingly technological work world and be fully integrated members of the society.

Since the mid-1980s, the trend has been the inclusion or inclusive education, in which the emphasis is placed on students with disabilities being included in regular education system. This inclusive model focuses on students belonging in general classrooms, and the successful inclusive education happens primarily through accepting, understanding, and attending to student's differences and diversity.

To achieve inclusion, it is necessary to be aware that all children and students have the capacity for learning and for educational development. Therefore, each school must find ways to deal with the difference, adapting teaching processes to the characteristics and conditions of each student, mobilizing the means at their disposal so that everyone learns and participates in the learning process. IT is crucial for people with disabilities and special educational needs and using them in schools to support inclusion can enable them to communicate, be included in lessons, be more autonomous, and learn more effectively (BECTA 2003).

Visual impairment (blindness, partial sight, and color blindness) is a disability category and includes the range from low vision, students who are partially sighted and can generally read print, to full blindness, the ones who are blind and cannot read print. Students with visual impairment, depending on their individual circumstances, “may not be able to rely on the sense of sight to obtain information, observe their surroundings, and learn about the world” (Presley and D’Andrea 2008, p. 4). The implications of not being able to use all visual capability can affect aspects of life and learning of students

with visual impairment. Thus, abstract reasoning and conceptual thinking are often problem areas for these students.

Visual impairment is inevitably associated with several limitations regarding electronic accessibility, but students with vision impairments cannot be excluded from technological evolution. Therefore, it is imperative that they benefit from technologies, promoting their digital inclusion, communication, autonomy, and involvement in learning.

Assistive Technology (AT) and Digital Technology

Information and communication technology (ICT) is a specific area of IT and when concerned with educational systems includes mainstream technologies, assistive technologies, media and accessible formats, educational software, and online learning environments (UNESCO 2011). Assistive technology is “software and technology which helps people with disabilities and special needs to overcome the additional challenges they face in communication and learning” (BECTA 2003, p. 3).

Technology innovations are a central factor to education. Much of the assistive technology for individuals with visual impairments has focus on accessing information (Kelly and Smith 2011); however, information technologies play several enabling roles for these students, such as enabling impairment compensation, accessing information, facilitating communication, assisting learning, arranging and sustaining support, increasing collaboration, and achieving social connection and participation (Pacheco et al. 2017). Yet, learners with visual impairment face difficulties with accessibility of websites, course learning management systems, and digital audio and video (Fichten et al. 2009b).

The first assistive technology devices were tools such as the slate and stylus, a handheld device, used to create braille. After these, manual braillewriters were developed, ensuring a faster production of texts with braille symbols, and in the early 1900s, audio technology, such as radios

and recorders, arose (Kelly and Smith 2011). With the technological development, new technologies for people with visual impairment have been developed: braille embossers, advanced close-circuit televisions (CCTVs), scanners and optical character recognition software, computer screen readers, compact discs, and many other innovations that can help people with visual impairment (Kelly and Smith 2011), such as speech synthesizers, talking book libraries, and mobility-aid solutions for mobile phones.

Nowadays, many technologies which aim to decrease the impact of visually impairment are under development. In 2017, during the Low Vision Awareness Month, the National Eye Institute, part of the USA National Institutes of Health, highlighted new technologies and tools to help the 4.1 million Americans with visual impairments; among them, the co-robotic cane, the robotic glove that finds door handles and small objects, the smartphone crosswalk app, and the CamIO (camera input-output) that provides real-time audio feedback as the user explores an object (DeMott 2017).

Students with visual impairment have also difficulty in accessing graphical materials (Butler et al. 2017). In order to overcome this barrier, students can use technologies such as sonification, haptic feedback, integrated e-book delivery on touchscreen, and three-dimensional printed tactile models (Simui et al. 2018). These technologies have been developed to help individuals with visual impairment to access graphical information, though not yet in extensive use (Simui et al. 2018).

However, and despite the wide range of technological resources, there are many barriers in receiving and using them by students with visual impairment due to internal and external factors. The lack of awareness, services, products, and financial barriers are some of the issues mentioned by researchers and international organizations (Bhatt and Kumari 2015; UNICEF and WHO 2015). Furthermore, students with visual impairment are reluctant to use these tools, once they face frustration and social embarrassment and do not want to draw attention to themselves for fear of failing to handle them properly (Bhatt and Kumari 2015).

Learning by Social Media Platforms

Besides ICT, IT also covers digital tools such as social media platforms, mobile devices, and applications, but yet, there is no empirical evidence of the role played by these last ones (Griffin-Shirley et al. 2017; Pacheco et al. 2017). Social networking services and portable devices are additional opportunities for accessing information and the preferred means of communication by students with visual impairment. These technological means are being used by these students as a complementary environment for informal and individualized learning (Pacheco et al. 2017). Computer mediates communication, both synchronous and asynchronous, and gives blind or partially sighted students the opportunity to participate actively in classroom activities, interact and communicate easily with their peers (Arrigo 2005).

Permvattana and Hollier (2013) refer that the ability to access online tutorials in YouTube, researching using Twitter, and sharing ideas using blogs conducts to benefits for education. The social network service Facebook is the most used networking service (Voykinska et al. 2016; Wu and Adamic 2014), and it is used as a communication channel, overcoming the constraints of time and space and making communication better and quicker (Pacheco et al. 2017). Wu and Adamic found that users with visual impairment “participate on Facebook (e.g. status update, comments, likes) as much as the general population, and receive more feedback (i.e., comments and likes) on average on their content” (2014, p. 3133). So, “students with vision impairments adapted social media to respond to their personal learning needs” (Pacheco et al. 2017, p. 8) and now use social media tools and applications to support online knowledge sharing and academic collaborations (Pacheco et al. 2017).

However, blind social networking services users face challenges in interacting with it due to “pervasive visual elements, complicated page structure, and infinitely scrolling feeds that are incompatible with screen readers” (Voykinska et al. 2016, p. 1593). Moreover, “the use of JavaScript to create highly dynamic web pages

can cause problems for screen readers, and bugs related to accessibility can be harder to capture and reproduce” (Wu and Adamic 2014, p. 3133). As a drawback, all these problems cannot be suppressed by the W3C Web Content Accessibility Guidelines alone, because it has guidelines to make content accessible to a wider range of people with disabilities (Buzzi et al. 2012).

Despite this, the evolution of information technology and the specific development of assistive technologies are removing barriers and enabling the same access to people with visual impairment as anyone (Wu and Adamic 2014). However, there is still much more that needs to be done to ensure universal accessibility to web content (Fichten et al. 2009a; Voykinska et al. 2016).

Learning Through E-learning

Though Internet is the main mean to access information, students with visual impairment appreciate “the fact that via ICTs they can search, retrieve and access a larger amount of information and from different sources” (Pacheco et al. 2017, p. 5). With the widespread of the Internet, it was possible to develop virtual learning environments and apply these systems in teaching and learning process. Nowadays, e-learning is becoming a valuable tool in visually impaired students’ learning process (Kharade and Peese 2012) and has the potential to facilitate inclusion of these students (Fichten et al. 2009a). Kharade and Peese define e-learning:

as the delivery of a learning, training or education programme by electronic means covering a wide set of applications and processes, such as web-based learning, computer-based learning, virtual classrooms and digital collaboration. (2012, p. 440)

The same authors consider that e-learning stimulate remote learning for students with visual impairment, enable teachers to provide remote assistance to these students, and promote continuing education for visual impaired adults. So, e-learning leads to “more effective and efficient methods for acquiring and transferring knowledge beyond the traditional classroom environments” (Buzzi et al. 2012, p. 125).

Learners with visual impairments must adapt and use e-learning, as this is one of the most used tools in postsecondary education by teachers to support the learning process (Fichten et al. 2009a). E-learning leads to the inclusion of students with visual impairments in classrooms, facilitating the access to class materials without assistance (Fichten et al. 2009a). However, Fichten et al. (2009b) observed that there is a reduced use of e-learning by teachers of learners with visual impairments in colleges and universities and they have lack of knowledge working with it.

Educational materials created for sighted students are often inappropriate for learners with visual impairments; therefore, these students with disabilities face particular challenges at an e-learning environment due to the unsuccessful support of assistive technologies and learning materials accessible issues (Fichten et al. 2009a; Permavattana and Hollier 2013). Educational materials should be provided through several means: visual, auditory, and tactile (Buzzi et al. 2012), making them accessible to everyone, including people with disabilities.

Teaching, Learning, and Information Technologies

According to Teles (2011), visual impairment is perhaps the most undervalued area concerned to information technologies and special educational needs. However, the access to appropriate technology enables learners with visual impairment to better adjust to the traditional learning processes and use of sources of information as their peers (Alves et al. 2009).

Students with visual impairment have the right to expect the same level of education just like any other students, but they face relevant difficulties in terms of accessing and using electronic learning tools and struggle to maintain the required learning pace, leading this to lower achievements (Eligi and Mwantimwa 2017; Permavattana and Hollier 2013). According to UNICEF and WHO, “the correlation between low education outcomes and having a disability is often much stronger than the correlations with other characteristics” (2015, p. 16).

Almost all education is going digital. Onukotun’s, cited by Eligi and Mwantimwa, reveals that information technologies “do not only enhance access to information but also promote education and lifelong learning” (2017, p. 88). Information technologies allow learners with visual impairment to access information and the general curriculum. They help to increase the independence of blind and partially sighted students, minimizing the deprivation of perceiving images, gestures, and colors. The use of computers, speech synthesizers, and screen magnifiers provide access and enable the production of digital information. Therefore, technologies are means to overcome the lack of vision, expanding opportunities to communicate and to develop personal autonomy; moreover, it stimulates cognitive development and enhances and leverages the appropriation of knowledge, skills, and information (Sá et al. 2007).

The speed on information processing by students with visual impairment is allowed and improved with the use of a screen reader for reading with audio support (Jackson 2012). Besides, it permits better understanding of texts, shortening the time required to complete the tasks (Jackson 2012; Pacheco et al. 2017). With the use of optical devices, research shows improvements in the students’ silent reading speeds and comprehension rates (Corn et al. 2002).

Many studies emphasize the potential of using IT in education of people with visual impairment (Bhatt and Kumari 2015; Fuglerud 2011; Jackson 2012; Kelly and Smith 2011; Pacheco et al. 2017; Papadopoulos and Goudiras 2005; Pattillo et al. 2004; Wu and Adamic 2014; Zhou et al. 2012); however, few schools and teachers implement information technologies to successfully support learning and teaching process (Nwigbo and BK 2016). In this sense and contrary to other studies, Bano et al. (2011) research shows that braille literacy, for their sample, was more important than the computer software literacy in the education of students with visual impairment, having more positive responses towards the first one. The dissatisfaction with the computer education at these students’ schools is highlighted in this research, as well as, the absence of teachers with technological required experience.

In schools, the means are not always available or suited to the real needs of students with or without special education needs (Ribeiro et al. 2010). It is crucial that schools ensure access to appropriate and necessary technology to students with visual impairment (Abner and Lahm 2002), but more importantly, suit technology to education goals and standards, and have a vision for the use of it to support the curriculum (Nwigbo and BK 2016). It is important these students with special educational needs learn to use assistive technology to access electronic information, so they can participate more equally with their sighted classmates (Presley and D'Andrea 2008).

By keeping an open mind, becoming comfortable about technology and its pervasive role in our lives, encouraging students to explore and use technology to the fullest extent possible, and promoting skills through opportunities for practice, professionals working with students who are visually impaired can help them to excel in today's competitive world – and tomorrow's as well. (Presley and D'Andrea 2008, p. 16)

IT supports new learning experiences for students with visual impairment, providing and improving this way a quality education (UNESCO 2011), a wide range of opportunities and the quality of the teaching and learning process (Fuglerud 2011). Broadly speaking, the actual challenge is to provide technological access and training (technology education) for the students with visual impairment to support learning and teaching (educational technology) (Nwigbo and BK 2016), making the best use of technology throughout their academic progression.

However, it is important to emphasize that technologies by themselves do not mediate learning but just provide influence on learning strategies, so it could not be thought as a global solution but “should be considered as a support to the learning process” (Söderberg and Fellenius 2000, p. 70).

Teachers' Role on Visually Impaired Learners' Education

Despite the increasing independency of learners with visual impairments, all teachers are prominent elements in their educational process and have an

important role to guide these students to overcome their difficulties and achieve academic success. Ramos and Andrade found on their study that teachers are aware that “ICT promote the transmission of knowledge and improve the teaching and learning process, contributing to academic success, autonomy and inclusion of students who are blind or partially sighted” (2016, p. 638).

However, many regular teachers are unprepared and fearful to deal with most of the tools and applications designed for students who are visually impaired (Ramos and Andrade 2016). This fact leads to a lower application of IT with learners with visual impairment (Ramos and Andrade 2016). Moreover, teachers are not reflecting IT on their daily classroom role due in part “to the pressures they perceived to meet their individual obligations of teaching a range of classes” (Hartnell-Young 2003, p. 2).

The use of IT by students who are visually impaired depends on the encouragement given by teachers and it is constrained by initial and continuous training acquired by those (Smith and Kelley 2007). Research indicate that teachers of learners with visual impairment do not have the necessary training on IT area (Abner and Lahm 2002; Ramos and Andrade 2016; Smith and Kelley 2007; Zhou et al. 2011); however, this lack of specific training is more severe for teachers in regular classroom than for special education teachers (Papadopoulos and Goudiras 2005). So, it is important that teachers get more training on how to work with visually impaired learners (Simui et al. 2018), as well as pedagogical support (Alves et al. 2009).

The teachers' lack of training is one of the significant problems which prevents them from achieving the full advantages of IT use in educational practices (Ribeiro et al. 2010). Teachers need time to plan, learn how to integrate technology and implement it (Nwigbo and BK 2016), thus taking advantage of their beliefs on IT potential as promoter of inclusive education (Alves et al. 2009; Ramos and Andrade 2016) and its positive impact on the curriculum (Nwigbo and BK 2016; Ramos and Andrade 2016).

With the current technological requirements and consequent application of IT at schools, it is a challenge for teachers to update and expand their

skills so that their educational activities benefit from the potential of technological resources. Although the use of IT in schools is taken seriously by governments and educational systems, “there appear to be more critical steps and vital ingredients needed for the successful infusion of ICT into educational environments” (Nwigbo and BK 2016, p. 1).

With the technological development, teachers’ role is changing, as well the traditional teaching methods have been challenged by technology-enhanced teaching and learning methods (Hämäläinen and Cattaneo 2015; Hartnell-Young 2003). According to the research findings, traditional teaching is diminishing and is arising the role of the teacher as a facilitator, guiding and coaching for students’ learning processes (Hämäläinen and Cattaneo 2015). The active role of teachers is becoming the booster to interaction processes related to learning tasks, and they are progressively working together with learners in new technology-enhanced learning contexts, such as technology-enhanced classrooms and virtual settings (Hämäläinen and Cattaneo 2015).

New Challenges to Teaching and Learning Process

IT allows students to achieve learning experiences “when and where they are needed” (Nwigbo and BK 2016, p. 5) and independency to what they learn. Besides, students making use of technology become more independent in the classroom and can discover solutions to problems both independently and collaboratively. Researches show that online interaction triggers the opportunity to share information from their peers (Pacheco et al. 2017). Therefore, IT promotes the cooperation and collaboration among learners within and beyond school, having a positive effect on teaching and learning process, “introducing news and better ways of learning and teaching” (Nwigbo and BK 2016, p. 6). Technology can support new types of learning possibilities (Hämäläinen and Cattaneo 2015), as well as promote students as active learners and with the desire of discovery and knowledge.

In education field, based on each individual student’s needs, cognitive computing services – data-driven artificial intelligence (AI) – provide content, planning, and intelligent activities to promote knowledge in an effective and personalized way. In fact, according to Coccoli, Maresca, and Stanganelli, “from the e-learning point of view [...], cognitive computing can be an accelerator for students’ achievements, and a valuable support for the teachers” (2016, p. 62).

Cognitive computing can either support teachers in solving common students’ issues, such as “school dropout, individualization of learning, customization of training path, etc., due to their capability of analysing data” (Coccoli et al. 2016, p.64). Teachers can adopt new tools of cognitive computing to conduct individualized experiences and provide a “range of activities to assist students to become critical thinkers, designers and problem solvers” (Nwigbo and BK 2016, p. 5).

Recently, several tools and platforms based on cognitive computing were created: Cognitive Reasoning Platform by Enterra; Deep Learning, by Microsoft; DeepMind, by Google; IDOL, delivered by HP; and Watson, by IBM. Digital interactions with students, promoted by these platforms, can enhance learners’ performances and help educators personalize and adapt their approaches to students’ results (Coccoli et al. 2016). To drive personalized teaching, IBM Watson Education offers teachers a new level of engagement and a detailed view of each student, including achievement, academic performance, attendance, behavior, and activities learned.

The mobile app market is growing, and it is providing accessible experiences for visually impaired smartphone users. Microsoft has released, on July 2017, the new free artificial intelligence application for Apple’s iPhone, called Seeing AI (formally known as Deep Vision), designed for the low-vision community. This app uses mobile camera and describes people, text, currency, color, and objects that are being photographed. This app can turn the visual world into an audible experience (Microsoft n.d.) and can be applied in educational context to overcome visual barriers faced by these learners.

Artificial intelligence can make the educational experience more effective and engaging, both for

students and teachers and “the current absence of sophisticated use of AI Technologies in schools, colleges, and universities may be explained by the lack of financial resources as well as the lack of data establishing the technologies’ effectiveness” (Stone et al. 2016, p. 33).

Virtual assistants, sometimes called smart speakers, from Amazon, Apple, Google, and Microsoft, such as Alexa, Siri, Google’s Assistant, and Cortana, respectively, are voice command platforms which can carry out a range of tasks. Therefore, applying these platforms in schools, students can interact with them and get real-time personal feedback. These can be useful in schools unlocking barriers for both students and teachers and a source of information and enhancing thought-provoking tasks. For example, these platforms can be used by learners with visual impairment to find library materials faster.

The arise of digital voice assistants in education is inevitable, so it is important that educational system explore how can it create more effective, engaging, and creative learning environment.

“New competencies are required by teachers of pupils with visual impairments in mainstream schools,” opposing these “from the traditional model of training dating from the time of the special school and the ‘sight class’ era” (Söderberg and Fellenius 2000, p. 69). To achieve the real potential of IT as well as the important educational goals of students with visual impairment, it is essential that educators use IT in learning situations (Alves et al. 2009; Presley and D’Andrea 2008).

Conclusions

From the viewpoint of the implementation of IT in visually and partially sighted students teaching and learning process, research studies indicate that IT enables students to overcome barriers of learning, as well as develop their inclusion in the mainstream classrooms. Applying them to support education can lead to educational benefits such as improving learning and increasing communication skills, yet, not all students have positive feelings towards IT daily educational use.

Thereby the continuous development of IT, its implementation, for educational purposes, with students with visual special needs, has a long way to go. Educational community must be open-minded to exceed the traditional teaching model and place greater emphasis on the active role of students with visual impairment inside and outside classroom, using the available technological means, even those which are behind educators’ comfort zone.

Even when technology is available, access may still be problematic. To avoid insecurity and frustration by students with visual impairment, dealing with accessible web issues, it is important to ensure full accessibility of the learning environment and the educational materials, following the W3C guidelines.

Therefore, material conditions of the schools should be strengthened, and a greater commitment must be done by the educational community, especially by teachers, to implement IT in learning and teaching process. Teachers refer barriers to the low use of technologies as a mean to optimize the learning process, such as time constraints; insufficient knowledge to adapt technological means to visually impaired learners’ needs, reinforced with the deficiency of training on this specific technological area.

They can maximize the impact of IT on teaching and learning process by understanding the potential of it to support students with visual impairment and tailoring and adapting activities to involve these students in learning. Online discussion forums can be used to access information, advice, and guidance, as well as to share knowledge and for reflection among teachers in regular classroom and special education teachers. It is utterly important that all community get involved in this process.

Introduction

It is believed that the business schools are driven by its traditional role of teaching from text books based on syllabus that is outdated (Schurman and Louis [2010](#)). The educational system must fulfill the need to create lifelong learners geared

to “add-value” in the knowledge-based economy (Bailie 2011). In fact, worldwide, the business schools are struggling hard to maintain their faculty brand. The faculty research output and efforts have also been criticized of late, with some business practitioners arguing that academic research is irrelevant (Bennis and Toole 2005). It is believed by the researchers today that research-based business education is a necessity for improving business practices. The roles of faculty increased from teaching to do research; from researchers to case writers; and from consultants to mentors. Furthermore, Indian business school faculty members actively participate in various administrative positions from time to time. This raises an important argument of how they will succeed in maintaining quality of competent faculty, particularly in research but also other competencies described above. The brand value of a business school may involve the brand value of faculty. Important factors like personality, ability, knowledge, and skills play an active role in determining the competencies of the faculty. They are required to generate skills to sustain in the world of collaborative alliances between business schools and industry (Ranjan and Tripathi 2010). Also, research output is valued in a knowledge economy.

The faculty members take enormous challenges, in terms of contents and web-based technologies, to understand and implement research teaching into integrated educational practices (Mason 2003; Hramiak 2005; Bailie 2011). They pursue scholarly academic research sometimes even in the absence of explicit financial returns, according to existing empirical evidence. There is literature that suggests that research and economic value creation for students are at least correlated (Friga et al. 2003; Mitra and Golder 2008; Rindova et al. 2005). Although the correlation may seem to be spurious but in reality, any BSF research activity not only results in student value creation but also directly impacts the ranking and image of the business school. The teaching paradigm for faculty to help students in finding place and purpose is very important (Chambers 2002). From the administration’s point of view, there is also a need for creating a bridge to the future by preparing faculty to face new challenges (Austin 2002).

Chambers (2002) analyzed the teaching paradigm for the development of faculty to help students in finding place and purpose. Austin 2002 identified the need for creating the bridge to the future by preparing new faculty to face changing expectation in shifting. Braskamp (2000) studied a holistic approach to assess faculty. Draganidis et al. (2006) implemented an ontology-based application that can be used for competency management. There were many related studies (Ranjan and Tripathi 2007a, 2008, 2010; Tripathi and Ranjan 2011, 2013) that dealt with some aspects of competency management in India for various educational institutions. This study extends the perspective to business school faculty.

Business School Faculty Competencies (BSFC)

The BSFC framework includes (1) obtaining competencies of faculty (2) understanding faculty roles and making a theoretical foundation (3) obtaining factors (6) validation and discussion. Exploratory research was being conducted to understand the significance of faculty competency management system and its underlying factors. In order to identify prototypical faculty dimensions, conducted qualitative research. Focus group discussions were held with academicians, and various educational consultants, and management consultants in education from different educational institutions and organizations. As a result, obtained a list of 16 variables that can influence a BSF. These elements were the basis for identifying competency-based management (CBM) process and quality in business schools. For an integrated view of an effective framework for the CBM, refer Fig. 1.

Business school faculty competency (BSFC) on the lines of Wrzesniewski and Dutton (2001), who defined job crafting, as the physical and cognitive changes individuals make in the task or relational boundaries of their work. Thus, it studied in this work how, when, and why BSF are likely to craft their jobs and roles, and how this will have impact on their identities and work meanings. For this

K

Knowledge Economy of Faculty Competencies of Indian Business School, Fig. 1 Competency-based management framework. (Adapted from Ranjan and Tripathi (2009))

purpose, assumed the principles of Fayol (2001) and designed 16 roles for faculty.

Competency-Based Management Framework Adapted

Motivation to craft a competency is more likely to spark crafting of competencies as faculty perceive that opportunities for competencies exist. Perceived opportunity to craft a competency refers to the sense of freedom or discretion faculty have in what they do in their competency and how they do it. Like other opportunity perceptions, opportunities to craft competency are psychologically

positive, since they imply a form of control, a sense of possible gain, and some sense of ability or means to act as described for employees and jobs by Jackson and Dutton (1988) and Lazarus and Folkman (1984). Thus, motivated faculty are likely to assess opportunities for all competency crafting at work before crafting their competencies.

The CBM model that defined in Fig. 1 sets forth the basic contribution to the type of competency roles that one business school faculty need to have, both of which are tied to the actual design of their work: (1) the level and form of task interdependence and (2) the level of discretion or freedom to craft competency, based on monitoring systems in the competency.

In any business school, faculty work with more or less task interdependence built into their work. This faculty competency is similar to the task defined by that states the extent to which the items or elements upon which work is performed so that changes in the state of one element affect the state of the others. Faculty engaged in competencies with higher degrees of interdependence are yoked more strongly to the timing and competencies of others, restricting the degree of possible task alterations, how the faculty perform using their competencies, and with whom they interact along the way. Thus, those with more task interdependence work under more constraints and have less freedom to alter task and relational boundaries as a result.

For example, a faculty who is bound to have institutional administration as competency cannot bring drastic changes and is constrained to work under limitations. Whereas a faculty whose competency is teaching, instructing, or researching is free to experiment with different methods of innovation. When faculty have many competencies like ability to be a good teacher, very good researcher, or to bring consulting opportunities, to communicate well with their peers and colleagues and students, such “super faculty” may perceive other competencies to be least important. The study argues that when faculty’ competency are explicitly defined and controlled, faculty may see more opportunity for crafting activities. This contradicts the job crafting model defined by changing any one of the roles the BSF can alter the design of the job and the social environment in which he or she works. By BSFC means how individuals define themselves at school similar to “work identity” defined by Wrzesniewski and Dutton (2001). As indicated by Ashforth and Mael (1989), while such identities cannot be changed at will, faculty may claim to have them and also why such a competency matters in the business school work place. Work identification, like business school identification, assumes correspondence between how individuals define themselves and how they define their work (Pratt 1998). When faculty interact, what role they play and which role makes them more effective is important. For example, if a faculty goes from

one role to another, say from alumni chairperson to research chairperson, then the meaning of the job and the identity and role change as well. IT believe changing roles have huge effect on the faculty competencies, though have not measured it the effectiveness of each change in each role in this study. The study identified the necessary roles for a faculty which drives the value of their competency.

The defined competencies for BSF if utilized effectively would lead to enhanced meaning in the work and BSF in fact would feel responsible. These competencies should be the prime parameter for faculty appraisals and promotions. The assert autonomy in the competency leads to perceived opportunities for BSF and encourages faculty to alter the task and relational boundaries of their competencies. This argument suggests that there are contradictory forces at play in the modern workplace that might affect competency crafting patterns. In Table 1, presents 16 roles of BSF competencies.

Managerial Implications of Business School Faculty(BSF)

The model competency identification for BSF offers significant contribution on how business schools think about and study their BSF. With the model of CBM, contributes to theories of BSF design by offering a new perspective on how competencies are constituted. The results specified the motivations, job, and individual features that create situations making CBM for BSF possible. The process proposed opens up different pathways for understanding how people channel their competencies and effectively shows that BSF can be competent designers of their work. This means BSF are more argentic than typically depicted in theories of job design. Rather than paint BSF as passive recipients of job tasks or of social information about job tasks, the CBM model indicates that BSF need to define their CBM roles for their jobs and use the feedback from these definitions to further motivate their CBM.

BSF competency and the roles are neither inherently good nor bad for business schools.

Knowledge Economy of Faculty Competencies of Indian Business School, Table 1 Faculty roles and their competencies

S. No.	Faculty roles	Brief description of faculty roles
1	Administrator/leader	Understanding the various administrative tasks that are associated with the implementation of education, training, and development activities. Need to provide the role of director, dean, chairperson, leadership, guidance for projects, alliances, partnerships, act as a chairperson to any academic domain. For example, chairperson of international relations, alumni committee, students affair council, research, etc.
2	Consultant	Faculty role as a consultant pulls more opportunity for industry institution interaction. It promotes more research opportunities Faculty role as a consultant brings more value to the classroom All faculty need to display academic excellence in classes. He/she has to undertake consultancy assignments and work towards bringing/engaging students using standard industry practices to IT companies, area-specific companies
3	Problem solver	Seeing organizations as dynamic, political, economic, and social systems which have multiple goals, using this larger perspective as a framework for understanding and influencing events and change. Faculty effectively organizing workshops, seminars, and conclaves and educating issues
4	Teacher	A faculty constantly needs to update himself/herself by attending various advanced educational programs like postdoctoral training programs, keeping abreast of new information and hence sharing the same with students. With primary objective of knowledge dissemination and knowledge sharing
5	Executor	All business school faculty need to display leadership skills in the sense while taking class, organizing events, in bringing training programs to institutions, in discussions and debates, one has to display enormous amount of leadership skills. All administrators may not be leaders. But all leaders have to display administrative skills. All administrators can be leaders if they hold a particular positions and need to maintain a high degree of professional leadership qualities
6	Mentor	The role of business school faculty will not be complete if he/she does not mentor students in nurturing and shaping in good direction
7	Editor/reviewer	For any business school faculty becoming a editorial member, editor or associated as reviewers to any good refereed journals in the world is a proud moment; it not only yields heavy networking contacts but it also promote up to date knowledge of processes, both industry and institutional developments in the world Faculty roles in editing, reviewing journals adds value to the development of action-based research; this exposes to world's different views of studies on the various issues of management
8	Researcher	Selecting, developing, and using methodologies, statistical and data collection techniques for a formal inquiry. This promoted action-based research outcome for both industry and institute
9	Team player	Knowing what factors inhibits team effectiveness and what can be done to promote teamwork. In business schools, all processes usually are done with teams from different teams. One has to be a good team player to imbibe the vision and mission of each team's objective
10	Executor	Each task provided by a business school to faculty are mostly tasks oriented, the faculty has to perfectly execute. Here the faculty need to display strong common sense and more timely inputs. He/she has to be a good executor
11	Planner	The faculty need to plan almost every operation he or she associated with. She has to plan the course, teaching methods, training programs, etc. Here all the planning methods that a faculty prepares need to be innovative, industry-based action research oriented, more creative, and she needs to deliver the same after planning. Else planning does not have any meaning if it does not delivered or executed
12	Evaluator	The faculty need to be a true evaluator of all processes like research outcomes, project outcomes, internship methods, alumni relational outcomes, placement processes, corporate linkages, student project evaluations, etc.

(continued)

Knowledge Economy of Faculty Competencies of Indian Business School, Table 1 (continued)

S. No.	Faculty roles	Brief description of faculty roles
13	Examiner	The faculty role as examiner is very crucial in the sense he/she needs to invigilate in exams, assess the performance, and examine the quality of student performance wise as well as behavior wise. She/he has to examine several proposals (for example, related to alliances and partnerships, training, and development)
14	Facilitator	Planning and coordinating logistics in an efficient and cost-effective manner. His facilitations as tutor, evaluator, and as such all the roles mentioned, he/she must do that maturely
15	Instructor	The business school faculty's primary role is an instructor. Teaching and research originate from this. When the faculty starts teaching, research ideas develop. The instruction methods that he/she uses
16	Communicator	The faculty need to bridge the gap between teaching and learning; for this, he needs to be an effective communicator. For complex educational problems, the faculty has to inspire

The degree to which BSF competency contribute to school branding, performance depends on the kinds of changes BSF make and on their roles. In this study suggested that BSF competency and their roles are one route by which BSF alter the meaning of work and forge new identities. If these meanings and identity constructions motivated behaviors that aligned individual work patterns of BSF, then BSF's CBM could be a net positive for any business school. However, if BSF competency altered connections to others or task boundaries in ways that were at odds with school objectives, then BSF competency might harm rather than enhance school effectiveness. BSF competency effects on schools that are also dependent on the systems in which individuals work.

To produce global leader, the mission of BSF is to provide students with the right mental and technical skills that are needed for their lifetime careers in business administration. Here BSF plays a very important role. In India, every business school generates information about students, courses, faculty and staff that includes managerial systems, organizational personnel, lecture details, quality research, and so on. This useful information, which serves as a strategic input, is very useful in improving the quality of the teaching of the faculty member and thus the quality educational process. BSF competency should be envisaged to be a special breed. A qualified BSF understands business situations and can correctly incorporate them into the learning process.

Without an effective way to brand the business school information collected, information about BSF often go underutilized. Parts of a collection can remain untapped for years, and the larger it grows, the more difficult its management becomes. Unfortunately, improving this usually comes at a cost – at a time when budget cuts have forced most of the faculty either quit or develop in-house research without exploring industry requirements. Each time the senior management and leadership change, it would have an adverse impact on faculty performance and roles. Lifelong learning, according to Aspin and Chapman (2001), is concerned with promoting skills and competences necessary for developing general capabilities and specific performance in work situations. This is just right for faculty skills and competences, as lifelong learning is vital for faculty performance in their tackling of precise job responsibilities and how well they can adapt their general and particular knowledge and competences to new tasks (Aspin and Chapman 2001).

In India, around 3500 business schools generate information about students, courses, faculty and staff that includes managerial systems, organizational personnel, lecture details, quality research, and so on. The BSF's CBM unfortunately are not focused. The authors emphasize that the developed framework would only serve as a reference or self-checking mechanism and would not bring a "miraculous change or transformation" in business schools. Setting up faculty

competency target parameters and awarding and rewarding faculty may not lead to faculty research outcomes, but if combined with clear documentation, consistent performance may well be a step in that direction, particularly if the system is aligned with mission and vision of the institute.

Competency Management for BSF

The competency of BSF can be accessed through knowledge behavior, administrative skills, institutional development activities, and research contributions. The roles of BSF in Table 1. Based on these roles, evaluate the faculty competencies. One may fulfill the knowledge criteria by satisfying the relevant subject knowledge and getting a great feedback received from students, but the faculty may lack in other competencies such as research, consultancy, institutional development activities, etc. Table 1 defines the roles and responsibilities of the faculty members developed by the authors.

The key is the ability to integrate BSF data efficiently and produce world class research and teaching standards that assist the B-schools in achieving its goals and ranks. This is important and essential for showing various government domains, accrediting bodies and other stakeholders who require periodic reports on the overall progress of their schools.

Conclusion

In business schools, there are many diverse heterogeneous faculty data is available. Faculty performance and their contribution drive any good business school. They don many different roles for the sustainable success of business school performance. The competencies can play a major role in examining and enhancing the effectiveness of business school faculty. The competence management performance assessment process of teaching and learning process is the biggest generator of information and knowledge as well in business school. It is clear that recognition of high

quality educational research by professors is dealt for students' admissions every year. The business schools have been making substantial investments for their faculty development programs to promote faculty roles. The regulatory bodies, accreditation bodies are seeking more information to measure and evaluate the effectiveness of the faculty.

Leadership on Information Technology in Education

Nina Abdul Razzak

Introduction

Since the beginning of the twenty-first century, many countries worldwide have been undergoing major social, cultural, and economic developments. In the process, these countries have come to realize that for sustainable economic development, relying mainly on natural resources is insufficient; what are needed, in addition, are “investments in knowledge that can facilitate technological innovation” (Tseng 2014 as cited in Abdul Razzak 2018). Consequently, we find many societies and economies shifting direction toward becoming knowledge and information-based, respectively.

A knowledge-based economy is an advanced economy in which there is greater reliance on information and high skill levels (OECD 2005); while, an information-based society is a society that relies on gaining competitive advantage internationally through major dependence on and use of data, information, knowledge, and Information Communication Technology (ICT) in creative and productive ways. (Abd.Mukti and Abd.Malik 2004; Abdul Razzak 2014, p. 62)

What this indicates is that currently economies are strongly and substantially correlated with ICT integration in every aspect of life (Abdul Razzak 2013), particularly in the field of education and training, in which the development of human skills and competencies required for preparing citizens for tomorrow’s workforce and employment challenges takes place (Abdul Razzak 2018).

ICT integration in education is also known as educational or instructional technology, and as a concept, it has been historically considered ambiguous to define; for its definition depends mainly on how the concept gets interpreted. Nevertheless, having a clear definition of the concept of educational technology and a description of what, as a practice, it entails is imperative for understanding a related important aspect currently found in almost every educational institution, namely that of technology leadership in education (Puckett 2014).

Technology leadership, as a fairly new style of leadership, has now become a necessity in educational institutions, since technological developments of this information age, along with the entry of digital technologies into educational institutions, have noticeably impacted educational systems in general, and teaching and learning processes in particular (Yorulmaz and Can 2016; Flanagan and Jacobsen 2003). This has in turn led to significant changes in the roles and responsibilities of teachers and administrators alike; as, they now find themselves in a position where they are

faced with the huge task of reshaping their educational organizations and practices in ways that better meet the needs of their societies, which have been considerably transformed by the new information age and the digital technologies that form it. The current roles and responsibilities of those in education now, therefore, require technological literacy on their part and include a widespread integration of ICT in almost every form of activity carried out in their institutions. Having a clear understanding of ICT integration in education is therefore crucial to them and to anyone interested in the topic, for that matter, especially when various interpretations of the concept exist in the literature and are in use in practice, and where some of those interpretations are more clear-cut than others.

Some interpretations of ICT integration in education have been simple and limited while others have been more complex and broad (Lakhana 2014). The simplest of interpretations restricts educational technology to applications of hard technology for the purpose of addressing problems in education. What hard technology refers to is mechanical and material tools, especially computers and computer programs. This limited interpretation of educational technology is problematic since it overlooks the human side and the reciprocity that exists between technology and the human intellect (Lakhana 2014). In other words, it fails to take intellectual and social significance into consideration, which usually focuses on the organization of knowledge for the achievement of practical purposes that assist human adaptation to, and participation in, the environment – and all this is done simultaneously through interrelationships with particular social values (Luppigini 2005). Nevertheless, this limited interpretation of educational technology dominates contemporary discussions and literature including governmental publications, in the form of an emphasis on the hardware, software, and tools utilized in the field (Lakhana 2014). The adoption of such an interpretation by any social scientist is something, obviously, farfetched for the simple reason of education being all about human constructs and social interactions. Besides, it is not possible to discuss or research any educational technology

issue without several cross-disciplinary views coming together (e.g., pedagogy, computer science, media technology, theory of knowledge, psychology, ethics, and quality assurance), among which many belong to the sphere of the social sciences (Balter 2017). This explains why more complex and broader interpretations of the concept exist, which usually consider educational technology as also including, in addition to hard technology, soft technology in the form of “immaterial tools, such as processes and ways of thinking” and address “the causal interdependence between intellectual growth and technological growth, whereby technology is not merely processes and tools, but is understood systemically” (Lakhana 2014, p. 2). These broader interpretations of the concept have over time led to evolving definitions of educational technology reflecting a history of social and technological change, whereby different definitions reflect different generations in time (Lakhana 2014). What this therefore signifies is a dynamic definition of educational technology that changes with the times rather than a static one, and this possibly explains why till now no universal definition of the concept exists. Despite this, however, various definitions of more or less the same flavor are widespread in the literature and are practically in use; some of these definitions are presented below.

Information Technology in Education

Definition of *Educational Technology*

As explained above, there are various definitions of *Educational Technology*; for example, the Association for Educational Communications and Technology (AECT) defines it as “the study and ethical practice of facilitating learning and improving performance by creating, using, and managing appropriate technological processes and resources” (2004, p. 1); whereas, the International Society of Technology Education (ISTE) defines it as “Devices, apps, webs, resources, internet access, technology support and other digital tools used to deepen learning.” Similarly, comparable definitions have been provided by many scholars and researchers, such as the definition of Spector (2012), which considers

educational technology as involving an application of knowledge that is orderly and well-organized, intended for the purpose of improving teaching, learning, and performance; or the definition of Brown (2014), which emphasizes the use of technology tools like SMART boards, electronic whiteboards, computers, videos, the Internet, BYOD (Bring Your Own Device), blogs, and social networking, to enhance student learning outcomes. A more comprehensive definition is provided by The George Lucas Educational Foundation: Edutopia (2007), which describes educational technology as “the use of technology resources in daily classroom practices and in the management of the school; it is achieved when the use of the technology is done routinely and in a transparent way and when technology is readily available and accessible to everyone in the school, supports the curricular goals, and helps students effectively learn and reach the 21st Century goals set for them” (cited by Abdul Razzak 2014, p. 61). Abdul Razzak (2013) builds on this definition by adding that educational technology involves three main components: (1) teachers and students learning how to use ICT, (2) teaching using ICT, and (3) students learning with and through ICT, which paves the way for the discussion of the necessary conditions needed for effective ICT integration in education; since, without these three components being in place, such integration would not be appropriate and may result in negative by-products (Abdul Razzak 2014; Flanagan and Jacobsen 2003).

Conditions for Effective Educational Technology

Although having a good technological infrastructure in an educational institution is necessary, research studies emphasize that it is not at all sufficient for effective ICT integration in education (Sadera 1997; Flanagan and Jacobsen 2003). Rather, many other conditions need to be met for ICT in education to be successfully implemented, among them: teachers and school administrators adopting a positive attitude toward such integration; believing in the usefulness of ICT in education; being provided with the suitable training for it; possessing relevant pedagogical and technological knowledge; being willing to abandon old

pedagogies, teaching methods, and ways of doing things; having sufficient confidence to try out innovations and take risks; and being provided with sufficient support (Abdul Razzak 2013). In fact, many researchers have suggested head-teachers’ or leadership preparation as being the most significant element in, and the best predictor of, the success of ICT integration in teaching and learning (Afshari et al. 2009; Kor et al. 2016). This is because technology integration is about change and involves a type of re-culturing, so that teaching and learning with ICT is accepted and actually adopted. In addition, every attempt of ICT integration in education presents a special case of change, since it usually takes place within a specific context that happens to have its individual peculiarities and challenges, and thus needs to be understood and carefully managed based on its own uniqueness. Accordingly, this calls for an astute and strong leadership that can ensure the smooth implementation of change and assist in overcoming any challenges (usually referred to as “barriers” in the literature) that are normally known to come along with implementing ICT integration (Abdul Razzak 2013). The question that poses itself here relates to the type or style of educational leadership that would best match the profile of a strong leadership for ICT integration in education. Before reaching an answer to this question, however, an explanation of leadership in education, including an exploration of the different educational leadership styles or models, is necessary.

Leadership in Education

Definition and Models of Educational Leadership

At its simplest, leadership can be defined as “a process whereby one individual influences a group of individuals to achieve a common goal (Northouse 2001)” (as cited in Seyal 2015, p. 32). What constitutes effective leadership, however, may differ from context to context (Bradley et al. 2017). In the realm of education, whether in a school or in a higher education institution (HEI), leadership is known as academic or educational leadership. At the school level, the principal or head-teacher is commonly thought of as the

educational leader; although, leadership is not confined to the principal, since even senior teachers (also called department heads) and classroom teachers are considered as educational leaders, or better yet as exhibitors of teacher/instructional leadership, when they clearly demonstrate leadership qualities or appear as champions in a particular area of competence. At the level of HEIs, things are a bit more complicated, not only because of the different structural levels that can exist within an institution (e.g., committee, department, college, university level) but also because of the multiplicity of administrative positions and academic ranks that can be in many cases intertwined. This makes it more difficult to specify who the educational leader/s in such a context usually is/are. In any case, educational leadership can be defined as “the distributed practice of carrying out the institution’s strategic vision while supporting the development of intellectual authority and a shared identity that fosters collegiality” (Bradley et al. 2017, p. 100). Since this definition encompasses vision as a core concept, then it emphasizes the pursuit of a better future for the whole organization, rather than merely stressing successful management of day-to-day activities, as formal *managerial educational leadership models* tend to do. In addition, by incorporating the ideas of distributed practice and a shared identity, this definition seems to extend from a collective model of educational leadership, in particular *the distributed leadership model*, which focuses on power sharing between staff members in the organization, who work collaboratively together in a trusting atmosphere, accepting to lead in their areas of expertise, and reach decisions together based on discussions, agreements, and consensus (Bush 2011). For this reason, this style of leadership is sometimes referred to as “the government of the many” (Lumby 2012), though without necessarily implying a reduction in the scope of the principal’s or senior administrator’s role (Bush 2011). Based on the definition provided, therefore, an educational leader’s role is to promote a shared identity that helps in sustaining the institution’s culture, core values, and goals that are aligned with its strategic vision, while at the same time leaving room within

it for intellectual freedom and individual and collaborative growth. Since educational leaders have to work with both administrative and academic staff and since they face a challenge of trying to strike a balance between administering resources, on the one hand, and promoting intellectual authority and the pursuit of scholarly goals on the other, then there is evidence that shared or distributed leadership may be a good fit for academic institutions (Bradley et al. 2017). This is because, through it, administrative tasks can be assigned to the nonteaching staff, while academic tasks and duties can be left in the hands of the academics to lead. This way, academics can be given more room to effectively focus on and set the direction for the job they were originally hired to do, whether in terms of teaching or research, without having to worry about bureaucratic demands that usually exist in the system (Bradley et al. 2017). For this reason, the distributed leadership model with the definitions of educational leadership that spring from it have been quite popular among scholars of the twenty-first century. Lumby (2012), nonetheless, admits that although distributed leadership is apparently suitable for the education sector, it is not common in educational institutions, which in practice tend to adopt more of a blended leadership approach that mixes between management and the efficient use of resources, on the one hand, and leadership on the other.

Other more classical educational leadership models are *the transactional* and *the transformational*. In transactional leadership, the focus is on gaining compliance of those in the organization through a system of motivation based on the exchange of rewards for the services they provide. This type of leadership therefore focuses on a contractual process of give and take, where the leader takes from the followers what is needed and gives them in return what they want. As long as the leaders’ needs are in accord with the followers’ wants, harmony prevails in the organization. Bush (2011) considers this type of leadership as more relevant to a political model of educational management, and Seyal (2015) views it as a leadership style more suited to stable work environments with little competition, which the

current changing educational environments of the information age are very far away from.
